Chapter 16

µC/OS-II Reference Manual

This chapter provides a reference to µC/OS-II services. Each of the user-accessible kernel services is presented in alphabetical order. The following information is provided for each of the services:

- A brief description
- The function prototype
- The filename of the source code
- The `#define` constant needed to enable the code for the service
- A description of the arguments passed to the function
- A description of the returned value(s)
- Specific notes and warnings on using the service
- One or two examples of how to use the function

OS_ENTER_CRITICAL()
OS_EXIT_CRITICAL()

Chapter	*File*	*Called from*	*Code enabled by*
3	OS_CPU.H	Task or ISR	N/A

OS_ENTER_CRITICAL() and OS_EXIT_CRITICAL() are macros used to disable and enable, respectively, the processor's interrupts.

Arguments

none

Returned Values

none

Notes/Warnings

1. These macros must be used in pairs.
2. If OS_CRITICAL_METHOD is set to 3, your code is assumed to have allocated local storage for a variable of type OS_CPU_SR, which is called cpu_sr, as follows

```
#if OS_CRITICAL_METHOD == 3      /* Allocate storage for CPU status
register */
    OS_CPU_SR  cpu_sr;
#endif
```

Example

```
void TaskX(void *pdata)
{
#if OS_CRITICAL_METHOD == 3
      OS_CPU_SR   cpu_sr;
 #endif

      for (;;) {
         .
         .
         OS_ENTER_CRITICAL();    /* Disable interrupts     */
         .                       /* Access critical code   */
         OS_EXIT_CRITICAL();     /* Enable  interrupts     */
         .
         .
      }
}
```

OSEventNameGet()

```
INT8U OSEventNameGet(OS_EVENT *pevent, char *pname, INT8U *err);
```

Chapter	File	Called from	Code enabled by
New in V2.60	OS_CORE.C	Task or ISR	OS_EVENT_NAME_SIZE

OSEventNameGet() allows you to obtain the name that you assigned to a semaphore, a mutex, a mailbox or a message queue. The name is an ASCII string and the size of the name can contain up to OS_EVENT_NAME_SIZE characters (including the NUL termination). This function is typically used by a debugger to allow associating a name to a resource.

Arguments

pevent is a pointer to the event control block. pevent can point either to a semaphore, a mutex, a mailbox or a queue. Where this function is concerned, the actual type is irrelevant. This pointer is returned to your application when the semaphore, mutex, mailbox or queue is created (see OSSemCreate(), OSMutexCreate(), OSMboxCreate() and OSQCreate()).

pname is a pointer to an ASCII string that will receive the name of the semaphore, mutex, mailbox or queue. The string must be able to hold at least OS_EVENT_NAME_SIZE characters (including the NUL character).

err a pointer to an error code and can be any of the following:

OS_NO_ERR	If the name of the semaphore, mutex, mailbox or queue was copied to the array pointed to by pname.
OS_ERR_EVENT_TYPE	You are not pointing to either a semaphore, mutex, mailbox or message queue.
OS_ERR_PEVENT_NULL	You passed a NULL pointer for pevent.

Returned Values

The size of the ASCII string placed in the array pointed to by pname or 0 if an error is encountered.

Notes/Warnings

1. The semaphore, mutex, mailbox or message queue must be created before you can use this function and obtain the name of the resource.

Example

```
char      PrinterSemName[30];
OS_EVENT *PrinterSem;

void Task (void *pdata)
{
    INT8U     err;
    INT8U     size;

    pdata = pdata;
    for (;;) {
        size = OSEventNameGet(PrinterSem, &PrinterSemName[0], &err);
        .
        .
    }
}
```

OSEventNameSet()

```
void OSEventNameSet(OS_EVENT *pevent, char *pname, INT8U *err);
```

Chapter	File	Called from	Code enabled by
New in V2.60	OS_CORE.C	Task or ISR	OS_EVENT_NAME_SIZE

OSEventNameSet() allows you to assign a name to a semaphore, a mutex, a mailbox or a message queue. The name is an ASCII string and the size of the name can contain up to OS_EVENT_NAME_SIZE characters (including the NUL termination). This function is typically used by a debugger to allow associating a name to a resource.

Arguments

pevent is a pointer to the event control block that you want to name. pevent can point either to a semaphore, a mutex, a mailbox or a queue. Where this function is concerned, the actual type is irrelevant. This pointer is returned to your application when the semaphore, mutex, mailbox or queue is created (see OSSemCreate(), OSMutexCreate(), OSMboxCreate() and OSQCreate()).

pname is a pointer to an ASCII string that contains the name for the resource. The size of the string must be smaller than or equal to OS_EVENT_NAME_SIZE characters (including the NUL character).

err a pointer to an error code and can be any of the following:

OS_NO_ERR	If the name of the semaphore, mutex, mailbox or queue was copied to the array pointed to by pname.
OS_ERR_EVENT_TYPE	You are not pointing to either a semaphore, mutex, mailbox or message queue.
OS_ERR_PEVENT_NULL	You passed a NULL pointer for pevent.

Returned Values

none

Notes/Warnings

1. The semaphore, mutex, mailbox or message queue must be created before you can use this function and set the name of the resource.

Example

```
OS_EVENT *PrinterSem;

void Task (void *pdata)
{
    INT8U  err;

    pdata = pdata;
    for (;;) {
        OSEventNameSet(PrinterSem, “Printer #1”, &err);
        .
        .
    }
}
```

OSFlagAccept()

```
OS_FLAGS OSFlagAccept(OS_FLAG_GRP *pgrp, OS_FLAGS flags, INT8U wait_type,
INT8U *err);
```

Chapter	File	Called from	Code enabled by
9	OS_FLAG.C	Task	OS_FLAG_EN && OS_FLAG_ACCEPT_EN

`OSFlagAccept()` allows you to check the status of a combination of bits to be either set or cleared in an event flag group. Your application can check for **any** bit to be set/cleared or **all** bits to be set/cleared. This function behaves exactly as `OSFlagPend()` does, except that the caller does NOT block if the desired event flags are not present.

Arguments

`pgrp` is a pointer to the event flag group. This pointer is returned to your application when the event flag group is created [see `OSFlagCreate()`].

`flags` is a bit pattern indicating which bit(s) (i.e., flags) you wish to check. The bits you want are specified by setting the corresponding bits in `flags`.

`wait_type` specifies whether you want **all** bits to be set/cleared or **any** of the bits to be set/cleared. You can specify the following arguments:

`OS_FLAG_WAIT_CLR_ALL`	You check **all** bits in `flags` to be clear (0)
`OS_FLAG_WAIT_CLR_ANY`	You check **any** bit in `flags` to be clear (0)
`OS_FLAG_WAIT_SET_ALL`	You check **all** bits in `flags` to be set (1)
`OS_FLAG_WAIT_SET_ANY`	You check **any** bit in `flags` to be set (1)

You can add `OS_FLAG_CONSUME` if you want the event flag(s) to be consumed by the call. For example, to wait for **any** flag in a group and then clear the flags that are present, set `wait_type` to

```
OS_FLAG_WAIT_SET_ANY + OS_FLAG_CONSUME
```

`err` a pointer to an error code and can be any of the following:

`OS_NO_ERR`	No error
`OS_ERR_EVENT_TYPE`	You are not pointing to an event flag group
`OS_FLAG_ERR_WAIT_TYPE`	You didn't specify a proper `wait_type` argument.
`OS_FLAG_INVALID_PGRP`	You passed a `NULL` pointer instead of the event flag handle.
`OS_FLAG_ERR_NOT_RDY`	The desired flags for which you are waiting are not available.

Returned Values

The flag(s) that cause the task to be ready or, 0 if either none of the flags are ready or an error occurred.

Notes/Warnings

1. The event flag group must be created before it is used.
2. This function does **not** block if the desired flags are not present.

IMPORTANT
The return value of `OSFlagAccept()` is different as of V2.70. In previous versions, `OSFlagAccept()` returned the current state of the flags and now, it returns the flag(s) that are ready, if any.

Example

```
#define  ENGINE_OIL_PRES_OK   0x01
#define  ENGINE_OIL_TEMP_OK   0x02
#define  ENGINE_START         0x04

OS_FLAG_GRP *EngineStatus;

void Task (void *pdata)
{
    INT8U     err;
    OS_FLAGS  value;

    pdata = pdata;
    for (;;) {
        value = OSFlagAccept(EngineStatus,
                             ENGINE_OIL_PRES_OK + ENGINE_OIL_TEMP_OK,
                             OS_FLAG_WAIT_SET_ALL,
                             &err);
        switch (err) {
            case OS_NO_ERR:
                 /* Desired flags are available */
                 break;

            case OS_FLAG_ERR_NOT_RDY:
                 /* The desired flags are NOT available */
                 break;
        }
        .
        .
    }
}
```

OSFlagCreate()

```
OS_FLAG_GRP *OSFlagCreate(OS_FLAGS flags, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
9	OS_FLAG.C	Task or startup code	OS_FLAG_EN

`OSFlagCreate()` is used to create and initialize an event flag group.

Arguments

`flags` contains the initial value to store in the event flag group.

`err` is a pointer to a variable that is used to hold an error code. The error code can be one of the following:

`OS_NO_ERR`	if the call is successful and the event flag group has been created.
`OS_ERR_CREATE_ISR`	if you attempt to create an event flag group from an ISR.
`OS_FLAG_GRP_DEPLETED`	if no more event flag groups are available. You need to increase the value of `OS_MAX_FLAGS` in `OS_CFG.H`.

Returned Values

A pointer to the event flag group if a free event flag group is available. If no event flag group is available, `OSFlagCreate()` returns a `NULL` pointer.

Notes/Warnings

1. Event flag groups must be created by this function before they can be used by the other services.

Example

```
OS_FLAG_GRP *EngineStatus;

void main (void)
{
    INT8U  err;

    .
    OSInit();         /* Initialize µC/OS-II */
    .
    .
                      /* Create a flag group containing the engine's status
*/
    EngineStatus = OSFlagCreate(0x00, &err);
    .
    .
    OSStart();        /* Start Multitasking  */
}
```

OSFlagDel()

```
OS_FLAG_GRP *OSFlagDel(OS_FLAG_GRP *pgrp, INT8U opt, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
9	OS_FLAG.C	Task	OS_FLAG_EN and OS_FLAG_DEL_EN

OSFlagDel() is used to delete an event flag group. This function is dangerous to use because multiple tasks could be relying on the presence of the event flag group. You should always use this function with great care. Generally speaking, before you delete an event flag group, you must first delete all the tasks that access the event flag group.

Arguments

pgrp is a pointer to the event flag group. This pointer is returned to your application when the event flag group is created [see OSFlagCreate()].

opt specifies whether you want to delete the event flag group only if there are no pending tasks (OS_DEL_NO_PEND) or whether you always want to delete the event flag group regardless of whether tasks are pending or not (OS_DEL_ALWAYS). In this case, all pending task are readied.

err is a pointer to a variable that is used to hold an error code. The error code can be one of the following:

OS_NO_ERR	if the call is successful and the event flag group has been deleted.
OS_ERR_DEL_ISR	if you attempt to delete an event flag group from an ISR.
OS_FLAG_INVALID_PGRP	if you pass a NULL pointer in pgrp.
OS_ERR_EVENT_TYPE	if pgrp is not pointing to an event flag group.
OS_ERR_INVALID_OPT	if you do not specify one of the two options mentioned in the opt argument.
OS_ERR_TASK_WAITING	if one or more task are waiting on the event flag group and you specify OS_DEL_NO_PEND.

Returned Values

A NULL pointer if the event flag group is deleted or pgrp if the event flag group is not deleted. In the latter case, you need to examine the error code to determine the reason for the error.

Notes/Warnings

1. You should use this call with care because other tasks might expect the presence of the event flag group.
2. This call can potentially disable interrupts for a long time. The interrupt-disable time is directly proportional to the number of tasks waiting on the event flag group.

Example

```
OS_FLAG_GRP *EngineStatusFlags;

void Task (void *pdata)
{
    INT8U        err;
    OS_FLAG_GRP *pgrp;

    pdata = pdata;
    while (1) {
        .
        .
        pgrp = OSFlagDel(EngineStatusFlags, OS_DEL_ALWAYS, &err);
        if (pgrp == (OS_FLAG_GRP *)0) {
            /* The event flag group was deleted */
        }
        .
        .
    }
}
```

OSFlagNameGet()

```
INT8U OSFlagNameGet(OS_FLAG_GRP *pgrp, char *pname, INT8U *err);
```

Chapter	File	Called from	Code enabled by
New in V2.60	OS_FLAG.C	Task or ISR	OS_FLAG_NAME_SIZE

`OSFlagNameGet()` allows you to obtain the name that you assigned to an event flag group. The name is an ASCII string and the size of the name can contain up to `OS_FLAG_NAME_SIZE` characters (including the `NUL` termination). This function is typically used by a debugger to allow associating a name to a resource.

Arguments

`pgrp` is a pointer to the event flag group.

`pname` is a pointer to an ASCII string that will receive the name of the event flag group. The string must be able to hold at least `OS_FLAG_NAME_SIZE` characters (including the `NUL` character).

`err` a pointer to an error code and can be any of the following:

`OS_NO_ERR`	If the name of the semaphore, mutex, mailbox or queue was copied to the array pointed to by `pname`.
`OS_ERR_EVENT_TYPE`	You are not pointing to either a semaphore, mutex, mailbox or message queue.
`OS_ERR_INVALID_PGRP`	You passed a `NULL` pointer for `pgrp`.

Returned Values

The size of the ASCII string placed in the array pointed to by `pname` or `0` if an error is encountered.

Notes/Warnings

1. The event flag group must be created before you can use this function and obtain the name of the resource.

Example

```
char         EngineStatusName[30];
OS_FLAG_GRP *EngineStatusFlags;

void Task (void *pdata)
{
    INT8U     err;
    INT8U     size;

    pdata = pdata;
    for (;;) {
        size = OSFlagNameGet(EngineStatusFlags, &EngineStatusName[0],
&err);
        .
        .
    }
}
```

OSFlagNameSet()

```
void OSFlagNameSet(OS_FLAG_GRP *pgrp, char *pname, INT8U *err);
```

Chapter	File	Called from	Code enabled by
New in V2.60	OS_FLAG.C	Task or ISR	OS_EVENT_NAME_SIZE

OSFlagNameSet() allows you to assign a name to an event flag group. The name is an ASCII string and the size of the name can contain up to OS_FLAG_NAME_SIZE characters (including the NUL termination). This function is typically used by a debugger to allow associating a name to a resource.

Arguments

pgrp is a pointer to the event flag group that you want to name. This pointer is returned to your application when the event flag group is created (see OSFlagCreate()).

pname is a pointer to an ASCII string that contains the name for the resource. The size of the string must be smaller than or equal to OS_EVENT_NAME_SIZE characters (including the NUL character).

err a pointer to an error code and can be any of the following:

OS_NO_ERR	If the name of the event flag group was copied to the array pointed to by pname.
OS_ERR_EVENT_TYPE	You are not pointing to an event flag group.
OS_ERR_INVALID_PGRP	You passed a NULL pointer for pgrp.

Returned Values

none

Notes/Warnings

1. The event flag group must be created before you can use this function to set the name of the resource.

Example

```
OS_FLAG_GRP *EngineStatus;

void Task (void *pdata)
{
    INT8U  err;

    pdata = pdata;
    for (;;) {
        OSFlagNameSet(EngineStatus, “Engine Status Flags”, &err);
        .
        .
    }
}
```

OSFlagPend()

```
OS_FLAGS OSFlagPend(OS_FLAG_GRP *pgrp,
                    OS_FLAGS     flags,
                    INT8U        wait_type,
                    INT16U       timeout,
                    INT8U       *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
9	OS_FLAG.C	Task only	OS_FLAG_EN

OSFlagPend() is used to have a task wait for a combination of conditions (i.e., events or bits) to be set (or cleared) in an event flag group. You application can wait for **any** condition to be set or cleared or for **all** conditions to be set or cleared. If the events that the calling task desires are not available, then the calling task is blocked until the desired conditions are satisfied or the specified timeout expires.

Arguments

pgrp is a pointer to the event flag group. This pointer is returned to your application when the event flag group is created [see OSFlagCreate()].

flags is a bit pattern indicating which bit(s) (i.e., flags) you wish to check. The bits you want are specified by setting the corresponding bits in flags.

wait_type specifies whether you want **all** bits to be set/cleared or **any** of the bits to be set/cleared. You can specify the following arguments:

OS_FLAG_WAIT_CLR_ALL	You check **all** bits in flags to be clear (0)
OS_FLAG_WAIT_CLR_ANY	You check **any** bit in flags to be clear (0)
OS_FLAG_WAIT_SET_ALL	You check **all** bits in flags to be set (1)
OS_FLAG_WAIT_SET_ANY	You check **any** bit in flags to be set (1)

You can also specify whether the flags are consumed by adding OS_FLAG_CONSUME to the wait_type. For example, to wait for **any** flag in a group and then **clear** the flags that satisfy the condition, set wait_type to

```
OS_FLAG_WAIT_SET_ANY + OS_FLAG_CONSUME
```

timeout allows the task to resume execution if the desired flag(s) is(are) not received from the event flag group within the specified number of clock ticks. A timeout value of 0 indicates that the task wants to wait forever for the flag(s). The maximum timeout is 65,535 clock ticks. The timeout value is not synchronized with the clock tick. The timeout count begins decrementing on the next clock tick, which could potentially occur immediately.

err is a pointer to an error code and can be:

OS_NO_ERR	No error.
OS_ERR_PEND_ISR	You try to call OSFlagPend from an ISR, which is not allowed.
OS_FLAG_INVALID_PGRP	You pass a NULL pointer instead of the event flag handle.
OS_ERR_EVENT_TYPE	You are not pointing to an event flag group.
OS_TIMEOUT	The flags are not available within the specified amount of time.
OS_FLAG_ERR_WAIT_TYPE	You don't specify a proper wait_type argument.

Returned Values

The flag(s) that cause the task to be ready or, 0 if either none of the flags are ready or an error occurred.

Notes/Warnings

1. The event flag group must be created before it's used.

IMPORTANT
The return value of `OSFlagPend()` is different as of V2.70. In previous versions, `OSFlagPend()` returned the current state of the flags and now, it returns the flag(s) that are ready, if any.

Example

```
#define  ENGINE_OIL_PRES_OK   0x01
#define  ENGINE_OIL_TEMP_OK   0x02
#define  ENGINE_START         0x04

OS_FLAG_GRP *EngineStatus;

void Task (void *pdata)
{
    INT8U     err;
    OS_FLAGS  value;

    pdata = pdata;
    for (;;) {
        value = OSFlagPend(EngineStatus,
                           ENGINE_OIL_PRES_OK   + ENGINE_OIL_TEMP_OK,
                           OS_FLAG_WAIT_SET_ALL + OS_FLAG_CONSUME,
                           10,
                           &err);
        switch (err) {
            case OS_NO_ERR:
              /* Desired flags are available */
                 break;

            case OS_TIMEOUT:
              /* The desired flags were NOT available before 10 ticks
occurred */
                 break;
        }
```

```
            .
            .
        }
    }
```

OSFlagPendGetFlagsRdy()

`OS_FLAGS OSFlagPendGetFlagsRdy(void)`

Chapter	*File*	*Called from*	*Code enabled by*
Added in V2.60	`OS_FLAG.C`	Task only	`OS_FLAG_EN`

`OSFlagPendGetFlagsRdy()` is used to obtain the flags that caused the current task to become ready to run. In other words, this function allows you to know "Who done It!"

Arguments

None

Returned Value

The value of the flags that caused the current task to become ready to run.

Notes/Warnings

1. The event flag group must be created before it's used.

Example

```
#define  ENGINE_OIL_PRES_OK   0x01
#define  ENGINE_OIL_TEMP_OK   0x02
#define  ENGINE_START         0x04

OS_FLAG_GRP *EngineStatus;

void Task (void *pdata)
{
    INT8U     err;
    OS_FLAGS  value;

    pdata = pdata;
    for (;;) {
        value = OSFlagPend(EngineStatus,
                           ENGINE_OIL_PRES_OK   + ENGINE_OIL_TEMP_OK,
                           OS_FLAG_WAIT_SET_ALL + OS_FLAG_CONSUME,
                           10,
                           &err);
        switch (err) {
            case OS_NO_ERR:
                 flags = OSFlagPendGetFlagsRdy();  /* Find out who made
task ready */
                 break;

            case OS_TIMEOUT:
                 /* The desired flags were NOT available before 10 ticks
occurred */
                 break;
        }
        .
        .
    }
}
```

OSFlagPost()

```
OS_FLAGS OSFlagPost(OS_FLAG_GRP *pgrp, OS_FLAGS flags, INT8U opt, INT8U
*err);
```

Chapter	*File*	*Called from*	*Code enabled by*
9	OS_FLAG.C	Task or ISR	OS_FLAG_EN

You set or clear event flag bits by calling `OSFlagPost()`. The bits set or cleared are specified in a *bit mask*. `OSFlagPost()` readies each task that has its desired bits satisfied by this call. You can set or clear bits that are already set or cleared.

Arguments

`pgrp` is a pointer to the event flag group. This pointer is returned to your application when the event flag group is created [see `OSFlagCreate()`].

`flags` specifies which bits you want set or cleared. If `opt` is `OS_FLAG_SET`, each bit that is set in `flags` sets the corresponding bit in the event flag group. For example to set bits 0, 4, and 5, you set `flags` to `0x31` (note, bit 0 is the least significant bit). If `opt` is `OS_FLAG_CLR`, each bit that is set in flags will **clears** the corresponding bit in the event flag group. For example to clear bits 0, 4, and 5, you specify `flags` as `0x31` (note, bit 0 is the least significant bit).

`opt` indicates whether the flags are set (`OS_FLAG_SET`) or cleared (`OS_FLAG_CLR`).

`err` is a pointer to an error code and can be:

`OS_NO_ERR`	The call is successful.
`OS_FLAG_INVALID_PGRP`	You pass a `NULL` pointer.
`OS_ERR_EVENT_TYPE`	You are not pointing to an event flag group.
`OS_FLAG_INVALID_OPT`	You specify an invalid option.

Returned Value

The new value of the event flags.

Notes/Warnings

1. Event flag groups must be created before they are used.
2. The execution time of this function depends on the number of tasks waiting on the event flag group. However, the execution time is deterministic.
3. The amount of time interrupts are **disabled** also depends on the number of tasks waiting on the event flag group.

Example

```
#define  ENGINE_OIL_PRES_OK   0x01
#define  ENGINE_OIL_TEMP_OK   0x02
#define  ENGINE_START         0x04

OS_FLAG_GRP  *EngineStatusFlags;

void  TaskX (void *pdata)
{
    INT8U  err;

    pdata = pdata;
    for (;;) {
        .
        .
        err = OSFlagPost(EngineStatusFlags, ENGINE_START, OS_FLAG_SET,
&err);
        .
        .
    }
}
```

OSFlagQuery()

```
OS_FLAGS OSFlagQuery(OS_FLAG_GRP *pgrp, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
9	OS_FLAG.C	Task or ISR	OS_FLAG_EN && OS_FLAG_QUERY_EN

`OSFlagQuery()` is used to obtain the current value of the event flags in a group. At this time, this function does **not** return the list of tasks waiting for the event flag group.

Arguments

`pgrp` is a pointer to the event flag group. This pointer is returned to your application when the event flag group is created [see `OSFlagCreate()`].

`err` is a pointer to an error code and can be:

`OS_NO_ERR`	The call is successful.
`OS_FLAG_INVALID_PGRP`	You pass a `NULL` pointer.
`OS_ERR_EVENT_TYPE`	You are not pointing to an event flag groups.

Returned Value

The state of the flags in the event flag group.

Notes/Warnings

1. The event flag group to query must be created.
2. You can call this function from an ISR.

Example

```
OS_FLAG_GRP *EngineStatusFlags;

void Task (void *pdata)
{
    OS_FLAGS flags;
    INT8U    err;

    pdata = pdata;
    for (;;) {
        .
        .
        flags = OSFlagQuery(EngineStatusFlags, &err);
        .
        .
    }
}
```

OSInit()

```
void OSInit(void);
```

Chapter	*File*	*Called from*	*Code enabled by*
3	OS_CORE.C	Startup code only	N/A

`OSInit()` initializes _C/OS-II and must be called prior to calling `OSStart()`, which actually starts multitasking.

Arguments

none

Returned Values

none

Notes/Warnings

1. `OSInit()` must be called before `OSStart()`.

Example

```
void main (void)
{
      .
      .
      OSInit();      /* Initialize µC/OS-II */
      .
      .
      OSStart();     /* Start Multitasking  */
}
```

OSIntEnter()

```
void OSIntEnter(void);
```

Chapter	*File*	*Called from*	*Code enabled by*
3	OS_CORE.C	ISR only	N/A

`OSIntEnter()` notifies _C/OS-II that an ISR is being processed, which allows µC/OS-II to keep track of interrupt nesting. `OSIntEnter()` is used in conjunction with `OSIntExit()`.

Arguments

none

Returned Values

none

Notes/Warnings

1. This function must not be called by task-level code.
2. You can increment the interrupt-nesting counter (`OSIntNesting`) directly in your ISR to avoid the overhead of the function call/return. It's safe to increment `OSIntNesting` in your ISR because interrupts are assumed to be disabled when `OSIntNesting` needs to be incremented.
3. You are allowed to nest interrupts up to 255 levels deep.

Example 1

(Intel 80x86, real mode, large model)

Use `OSIntEnter()` for backward compatibility with µC/OS.

```
     ISRx PROC   FAR
          PUSHA                          ; Save interrupted task's context
          PUSH   ES
          PUSH   DS
;
          CALL   FAR PTR _OSIntEnter     ; Notify µC/OS-II of start of ISR
          .
          .
          POP    DS                      ; Restore processor registers
          POP    ES
          POPA
          IRET                           ; Return from interrupt
     ISRx ENDP
```

Example 2

(Intel 80x86, real mode, large model)

```
    ISRx    PROC   FAR
            PUSHA                          ; Save interrupted task's
context
            PUSH   ES
            PUSH   DS
;
            MOV    AX, SEG(_OSIntNesting)  ; Reload DS
            MOV    DS, AX
;
            INC    BYTE PTR _OSIntNesting  ; Notify µC/OS-II of start of
ISR
            .
            .
            .
            POP    DS                      ; Restore processor registers
            POP    ES
            POPA
            IRET                           ; Return from interrupt
    ISRx    ENDP
```

OSIntExit()

```
void OSIntExit(void);
```

Chapter	*File*	*Called from*	*Code enabled by*
3	OS_CORE.C	ISR only	N/A

`OSIntExit()` notifies µC/OS-II that an ISR is complete, which allows µC/OS-II to keep track of interrupt nesting. `OSIntExit()` is used in conjunction with `OSIntEnter()`. When the last nested interrupt completes, `OSIntExit()` determines if a higher priority task is ready to run, in which case, the interrupt returns to the higher priority task instead of the interrupted task.

Arguments

none

Returned Value

none

Notes/Warnings

1. This function must not be called by task-level code. Also, if you decided to increment `OSIntNesting`, you still need to call `OSIntExit()`.

Example

(Intel 80x86, real mode, large model)

```
ISRx    PROC    FAR
        PUSHA                       ; Save processor registers
        PUSH    ES
        PUSH    DS
        .
        .
        CALL    FAR PTR _OSIntExit ; Notify µC/OS-II of end of ISR
        POP     DS                  ; Restore processor registers
        POP     ES
        POPA
        IRET                        ; Return to interrupted task
ISRx    ENDP
```

OSMboxAccept()

```
void *OSMboxAccept(OS_EVENT *pevent);
```

Chapter	*File*	*Called from*	*Code enabled by*
10	OS_MBOX.C	Task or ISR	OS_MBOX_EN && OS_MBOX_ACCEPT_EN

`OSMboxAccept()` allows you to see if a message is available from the desired mailbox. Unlike `OSMboxPend()`, `OSMboxAccept()` does not suspend the calling task if a message is not available. In other words, `OSMboxAccept()` is non-blocking. If a message is available, the message is returned to your application, and the content of the mailbox is cleared. This call is typically used by ISRs because an ISR is not allowed to wait for a message at a mailbox.

Arguments

`pevent` is a pointer to the mailbox from which the message is received. This pointer is returned to your application when the mailbox is created [see `OSMboxCreate()`].

Returned Value

A pointer to the message if one is available; `NULL` if the mailbox does not contain a message.

Notes/Warnings

1. Mailboxes must be created before they are used.

Example

```
OS_EVENT *CommMbox;

void Task (void *pdata)
{
    void *msg;

    pdata = pdata;
    for (;;) {
        msg = OSMboxAccept(CommMbox); /* Check mailbox for a message */
        if (msg != (void *)0) {
          .                           /* Message received, process   */
          .
        } else {
          .                           /* Message not received, do .. */
          .                           /* .. something else */
        }
       .
       .
    }
}
```

OSMboxCreate()

```
OS_EVENT *OSMboxCreate(void *msg);
```

Chapter	*File*	*Called from*	*Code enabled by*
10	OS_MBOX.C	Task or startup code	OS_MBOX_EN

`OSMboxCreate()` creates and initializes a mailbox. A mailbox allows tasks or ISRs to send a pointer-sized variable (message) to one or more tasks.

Arguments

`msg` is used to initialize the contents of the mailbox. The mailbox is empty when `msg` is a `NULL` pointer. The mailbox initially contains a message when `msg` is non-`NULL`.

Returned Value

A pointer to the event control block allocated to the mailbox. If no event control block is available, `OSMboxCreate()` returns a `NULL` pointer.

Notes/Warnings

1. Mailboxes must be created before they are used.

Example

```
OS_EVENT *CommMbox;

void main (void)
{
        .
        .
        OSInit();                              /* Initialize µC/OS-II  */
        .
        .
        CommMbox = OSMboxCreate((void *)0);    /* Create COMM mailbox  */
        OSStart();                             /* Start Multitasking   */
}
```

OSMboxDel()

```
OS_EVENT *OSMboxDel(OS_EVENT *pevent, INT8U opt, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
10	OS_MBOX.C	Task	OS_MBOX_EN and OS_MBOX_DEL_EN

`OSMboxDel()` is used to delete a message mailbox. This function is dangerous to use because multiple tasks could attempt to access a deleted mailbox. You should always use this function with great care. Generally speaking, before you delete a mailbox, you must first delete all the tasks that can access the mailbox.

Arguments

`pevent` is a pointer to the mailbox. This pointer is returned to your application when the mailbox is created [see `OSMboxCreate()`].

`opt` specifies whether you want to delete the mailbox only if there are no pending tasks (`OS_DEL_NO_PEND`) or whether you always want to delete the mailbox regardless of whether tasks are pending or not (`OS_DEL_ALWAYS`). In this case, all pending task are readied.

`err` is a pointer to a variable that is used to hold an error code. The error code can be one of the following:

`OS_NO_ERR`	if the call is successful and the mailbox has been deleted.
`OS_ERR_DEL_ISR`	if you attempt to delete the mailbox from an ISR.
`OS_ERR_INVALID_OPT`	if you don't specify one of the two options mentioned in the `opt` argument.
`OS_ERR_TASK_WAITING`	One or more tasks is waiting on the mailbox.
`OS_ERR_EVENT_TYPE`	if `pevent` is not pointing to a mailbox.
`OS_ERR_PEVENT_NULL`	if no more `OS_EVENT` structures are available.

Returned Value

A `NULL` pointer if the mailbox is deleted or `pevent` if the mailbox is not deleted. In the latter case, you need to examine the error code to determine the reason.

Notes/Warnings

1. You should use this call with care because other tasks might expect the presence of the mailbox.
2. Interrupts are disabled when pended tasks are readied, which means that interrupt latency depends on the number of tasks that are waiting on the mailbox.
3. `OSMboxAccept()` callers do not know that the mailbox has been deleted.

Example

```
OS_EVENT *DispMbox;

void Task (void *pdata)
{
    INT8U  err;

    pdata = pdata;
    while (1) {
        .
        .
        DispMbox = OSMboxDel(DispMbox, OS_DEL_ALWAYS, &err);
        if (DispMbox == (OS_EVENT *)0) {
            /* Mailbox has been deleted */
        }
        .
        .
    }
}
```

OSMboxPend()

```
void *OSMboxPend(OS_EVENT *pevent, INT16U timeout, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
10	OS_MBOX.C	Task only	OS_MBOX_EN

OSMboxPend() is used when a task expects to receive a message. The message is sent to the task either by an ISR or by another task. The message received is a pointer-sized variable, and its use is application specific. If a message is present in the mailbox when OSMboxPend() is called, the message is retrieved, the mailbox is emptied, and the retrieved message is returned to the caller. If no message is present in the mailbox, OSMboxPend() suspends the current task until either a message is received or a user-specified timeout expires. If a message is sent to the mailbox and multiple tasks are waiting for the message, µC/OS-II resumes the highest priority task waiting to run. A pended task that has been suspended with OSTaskSuspend() can receive a message. However, the task remains suspended until it is resumed by calling OSTaskResume().

Arguments

pevent is a pointer to the mailbox from which the message is received. This pointer is returned to your application when the mailbox is created [see OSMboxCreate()].

timeout allows the task to resume execution if a message is not received from the mailbox within the specified number of clock ticks. A timeout value of 0 indicates that the task wants to wait forever for the message. The maximum timeout is 65,535 clock ticks. The timeout value is not synchronized with the clock tick. The timeout count begins decrementing on the next clock tick, which could potentially occur immediately.

err is a pointer to a variable that holds an error code. OSMboxPend() sets *err to one of the following:

OS_NO_ERR	if a message is received.
OS_TIMEOUT	if a message is not received within the specified timeout period.
OS_ERR_EVENT_TYPE	if pevent is not pointing to a mailbox.
OS_ERR_PEND_ISR	if you call this function from an ISR and µC/OS-II suspends it. In general, you should not call OSMboxPend() from an ISR, but _C/OS-II checks for this situation anyway.
OS_ERR_PEVENT_NULL	if pevent is a NULL pointer.

Returned Value

OSMboxPend() returns the message sent by either a task or an ISR, and *err is set to OS_NO_ERR. If a message is not received within the specified timeout period, the returned message is a NULL pointer, and *err is set to OS_TIMEOUT.

Notes/Warnings

1. Mailboxes must be created before they are used.
2. You should not call OSMboxPend() from an ISR.

Example

```
OS_EVENT *CommMbox;

void CommTask(void *pdata)
{
      INT8U  err;
      void  *msg;

      pdata = pdata;
      for (;;) {
         .
         .
         msg = OSMboxPend(CommMbox, 10, &err);
         if (err == OS_NO_ERR) {
             .
             .  /* Code for received message                    */
             .
         } else {
             .
             .  /* Code for message not received within timeout */
             .
         }
         .
         .
      }
}
```

OSMboxPost()

```
INT8U OSMboxPost(OS_EVENT *pevent, void *msg);
```

Chapter	*File*	*Called from*	*Code enabled by*
10	OS_MBOX.C	Task or ISR	OS_MBOX_EN && OS_MBOX_POST_EN

OSMboxPost() sends a message to a task through a mailbox. A message is a pointer-sized variable and, its use is application specific. If a message is already in the mailbox, an error code is returned indicating that the mailbox is full. OSMboxPost() then immediately returns to its caller, and the message is not placed in the mailbox. If any task is waiting for a message at the mailbox, the highest priority task waiting receives the message. If the task waiting for the message has a higher priority than the task sending the message, the higher priority task is resumed, and the task sending the message is suspended. In other words, a context switch occurs.

Arguments

pevent is a pointer to the mailbox into which the message is deposited. This pointer is returned to your application when the mailbox is created [see OSMboxCreate()].

msg is the actual message sent to the task. msg is a pointer-sized variable and is application specific. You must never post a NULL pointer because this pointer indicates that the mailbox is empty.

Returned Value

OSMboxPost() returns one of these error codes:

OS_NO_ERR	if the message is deposited in the mailbox.
OS_MBOX_FULL	if the mailbox already contains a message.
OS_ERR_EVENT_TYPE	if pevent is not pointing to a mailbox.
OS_ERR_PEVENT_NULL	if pevent is a pointer to NULL.
OS_ERR_POST_NULL_PTR	if you are attempting to post a NULL pointer. By convention a NULL pointer is not supposed to point to anything.

Notes/Warnings

1. Mailboxes must be created before they are used.
2. You must never post a NULL pointer because this pointer indicates that the mailbox is empty.

Example

```
OS_EVENT *CommMbox;
INT8U     CommRxBuf[100];

void CommTaskRx (void *pdata)
{
      INT8U  err;

      pdata = pdata;
      for (;;) {
         .
         .
          err = OSMboxPost(CommMbox, (void *)&CommRxBuf[0]);
         .
         .
      }
}
```

OSMboxPostOpt()

```
INT8U OSMboxPostOpt(OS_EVENT *pevent, void *msg, INT8U opt);
```

Chapter	*File*	*Called from*	*Code enabled by*
10	OS_MBOX.C	Task or ISR	OS_MBOX_EN and OS_MBOX_POST_OPT_EN

`OSMboxPostOpt()` works just like `OSMboxPost()` except that it allows you to post a message to **multiple** tasks. In other words, `OSMboxPostOpt()` allows the message posted to be broadcast to **all** tasks waiting on the mailbox. `OSMboxPostOpt()` can actually replace `OSMboxPost()` because it can emulate `OSMboxPost()`.

`OSMboxPostOpt()` is used to send a message to a task through a mailbox. A message is a pointer-sized variable, and its use is application specific. If a message is already in the mailbox, an error code is returned indicating that the mailbox is full. `OSMboxPostOpt()` then immediately returns to its caller, and the message is not placed in the mailbox. If any task is waiting for a message at the mailbox, `OSMboxPostOpt()` allows you either to post the message to the highest priority task waiting at the mailbox (`opt` set to `OS_POST_OPT_NONE`) or to all tasks waiting at the mailbox (`opt` is set to `OS_POST_OPT_BROADCAST`). In either case, scheduling occurs and, if any of the tasks that receives the message have a higher priority than the task that is posting the message, then the higher priority task is resumed, and the sending task is suspended. In other words, a context switch occurs.

Arguments

`pevent` is a pointer to the mailbox. This pointer is returned to your application when the mailbox is created [see `OSMboxCreate()`].

`msg` is the actual message sent to the task(s). `msg` is a pointer-sized variable and is application specific. You must never post a `NULL` pointer because this pointer indicates that the mailbox is empty.

`opt` specifies whether you want to send the message to the highest priority task waiting at the mailbox (when `opt` is set to `OS_POST_OPT_NONE`) or to **all** tasks waiting at the mailbox (when `opt` is set to `OS_POST_OPT_BROADCAST`).

Returned Value

`err` is a pointer to a variable that is used to hold an error code. The error code can be one of the following:

`OS_NO_ERR`	if the call is successful and the message has been sent.
`OS_MBOX_FULL`	if the mailbox already contains a message. You can only send **one** message at a time to a mailbox, and thus the message **must** be consumed before you are allowed to send another one.
`OS_ERR_EVENT_TYPE`	if `pevent` is not pointing to a mailbox.
`OS_ERR_PEVENT_NULL`	if `pevent` is a `NULL` pointer.
`OS_ERR_POST_NULL_PTR`	if you are attempting to post a `NULL` pointer. By convention, a `NULL` pointer is not supposed to point to anything.

Notes/Warnings

1. Mailboxes must be created before they are used.
2. You must **never** post a `NULL` pointer to a mailbox because this pointer indicates that the mailbox is empty.
3. If you need to use this function and want to reduce code space, you can disable code generation of `OSMboxPost()` because `OSMboxPostOpt()` can emulate `OSMboxPost()`.
4. The execution time of `OSMboxPostOpt()` depends on the number of tasks waiting on the mailbox if you set `opt` to `OS_POST_OPT_BROADCAST`.

Example

```
OS_EVENT *CommMbox;
INT8U     CommRxBuf[100];

void CommRxTask (void *pdata)
{
    INT8U  err;

    pdata = pdata;
    for (;;) {
        .
        .
        err = OSMboxPostOpt(CommMbox, (void *)&CommRxBuf[0],
OS_POST_OPT_BROADCAST);
        .
        .
    }
}
```

OSMboxQuery()

```
INT8U OSMboxQuery(OS_EVENT *pevent, OS_MBOX_DATA *pdata);
```

Chapter	*File*	*Called from*	*Code enabled by*
10	OS_MBOX.C	Task or ISR	OS_MBOX_EN && OS_MBOX_QUERY_EN

OSMboxQuery() obtains information about a message mailbox. Your application must allocate an OS_MBOX_DATA data structure, which is used to receive data from the event control block of the message mailbox. OSMboxQuery() allows you to determine whether any tasks are waiting for a message at the mailbox and how many tasks are waiting (by counting the number of 1s in the .OSEventTbl[] field). You can also examine the current contents of the mailbox. Note that the size of .OSEventTbl[] is established by the #define constant OS_EVENT_TBL_SIZE (see uCOS_II.H).

Arguments

pevent is a pointer to the mailbox. This pointer is returned to your application when the mailbox is created [see OSMboxCreate()].

pdata is a pointer to a data structure of type OS_MBOX_DATA, which contains the following fields:

```
void  *OSMsg;                  /* Copy of the message stored in the
mailbox */
INT8U  OSEventTbl[OS_EVENT_TBL_SIZE];     /* Copy of the mailbox wait list
*/
INT8U  OSEventGrp;
```

Returned Value

OSMboxQuery() returns one of these error codes:

OS_NO_ERR	if the call is successful.
OS_ERR_PEVENT_NULL	if pevent is a NULL pointer.
OS_ERR_EVENT_TYPE	if you don't pass a pointer to a message mailbox.

Notes/Warnings

1. Message mailboxes must be created before they are used.

Example

```
OS_EVENT *CommMbox;

void Task (void *pdata)
{
      OS_MBOXDATA mbox_data;
      INT8U       err;

      pdata = pdata;
      for (;;) {
         .
         .
         err = OSMboxQuery(CommMbox, &mbox_data);
         if (err == OS_NO_ERR) {
           .   /* Mailbox contains a message if mbox_data.OSMsg is
not NULL*/
         }
         .
         .
      }
}
```

OSMemCreate()

```
OS_MEM *OSMemCreate(void *addr, INT32U nblks, INT32U blksize, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
12	OS_MEM.C	Task or startup code	OS_MEM_EN

`OSMemCreate()` creates and initializes a memory partition. A memory partition contains a user-specified number of fixed-size memory blocks. Your application can obtain one of these memory blocks and, when done, release the block back to the partition.

Arguments

`addr` is the address of the start of a memory area that is used to create fixed-size memory blocks. Memory partitions can be created either using static arrays or `malloc()` during startup.

`nblks` contains the number of memory blocks available from the specified partition. You must specify at least two memory blocks per partition.

`blksize` specifies the size (in bytes) of each memory block within a partition. A memory block must be large enough to hold at least a pointer.

`err` is a pointer to a variable that holds an error code. `OSMemCreate()` sets `*err` to:

`OS_NO_ERR`	if the memory partition is created successfully
`OS_MEM_INVALID_ADDR`	if you are specifying an invalid address (i.e., `addr` is a `NULL` pointer)
`OS_MEM_INVALID_PART`	if a free memory partition is not available
`OS_MEM_INVALID_BLKS`	if you don't specify at least two memory blocks per partition
`OS_MEM_INVALID_SIZE`	if you don't specify a block size that can contain at least a pointer variable

Returned Value

`OSMemCreate()` returns a pointer to the created memory-partition control block if one is available. If no memory-partition control block is available, `OSMemCreate()` returns a `NULL` pointer.

Notes/Warnings

1. Memory partitions must be created before they are used.

Example

```
OS_MEM *CommMem;
INT8U   CommBuf[16][128];

void main (void)
{
      INT8U err;

      OSInit();                          /* Initialize µC/OS-II           */
      .
      .
      CommMem = OSMemCreate(&CommBuf[0][0], 16, 128, &err);
      .
      .
      OSStart();                         /* Start Multitasking            */
}
```

OSMemGet()

```
void *OSMemGet(OS_MEM *pmem, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
12	OS_MEM.C	Task or ISR	OS_MEM_EN

OSMemGet obtains a memory block from a memory partition. It is assumed that your application knows the size of each memory block obtained. Also, your application must return the memory block [using OSMemPut()] when it no longer needs it. You can call OSMemGet() more than once until all memory blocks are allocated.

Arguments

pmem is a pointer to the memory-partition control block that is returned to your application from the OSMemCreate() call.

err is a pointer to a variable that holds an error code. OSMemGet() sets *err to one of the following:

OS_NO_ERR	if a memory block is available and returned to your application.
OS_MEM_NO_FREE_BLKS	if the memory partition doesn't contain any more memory blocks to allocate.
OS_MEM_INVALID_PMEM	if pmem is a NULL pointer.

Returned Value

OSMemGet() returns a pointer to the allocated memory block if one is available. If no memory block is available from the memory partition, OSMemGet() returns a NULL pointer.

Notes/Warnings

1. Memory partitions must be created before they are used.

Example

```
OS_MEM *CommMem;

void Task (void *pdata)
{
       INT8U *msg;

       pdata = pdata;
       for (;;) {
          msg = OSMemGet(CommMem, &err);
          if (msg != (INT8U *)0) {
             .                        /* Memory block allocated, use it. */
             .
          }
          .
          .
       }
}
```

OSMemNameGet()

```
INT8U OSMemNameGet(OS_MEM *pmem, char *pname, INT8U *err);
```

Chapter	File	Called from	Code enabled by
New in V2.60	OS_MEM.C	Task or ISR	OS_MEM_NAME_SIZE

`OSMemNameGet()` allows you to obtain the name that you assigned to a memory partition. The name is an ASCII string and the size of the name can contain up to `OS_MEM_NAME_SIZE` characters (including the `NUL` termination). This function is typically used by a debugger to allow associating a name to a resource.

Arguments

`pmem` is a pointer to the memory partition.

`pname` is a pointer to an ASCII string that will receive the name of the memory partition. The string must be able to hold at least `OS_MEM_NAME_SIZE` characters (including the `NUL` character).

`err` a pointer to an error code and can be any of the following:

`OS_NO_ERR`	If the name of the semaphore, mutex, mailbox or queue was copied to the array pointed to by `pname`.
`OS_ERR_INVALID_PMEM`	You passed a `NULL` pointer for `pmem`.

Returned Values

The size of the ASCII string placed in the array pointed to by `pname` or `0` if an error is encountered.

Notes/Warnings

1. The memory partition must be created before you can use this function and obtain the name of the resource.

Example

```
OS_MEM  *CommMem;
char     CommMemName[OS_MEM_NAME_SIZE];

void Task (void *pdata)
{
    INT8U     err;
    INT8U     size;

    pdata = pdata;
    for (;;) {
        size = OSMemNameGet(CommMem, & CommMemName [0], &err);
        .
        .
    }
}
```

OSMemNameSet()

```
void OSMemNameSet(OS_MEM *pmem, char *pname, INT8U *err);
```

Chapter	File	Called from	Code enabled by
New in V2.60	OS_MEM.C	Task or ISR	OS_MEM_NAME_SIZE

`OSMemNameSet()` allows you to assign a name to a memory partition. The name is an ASCII string and the size of the name can contain up to `OS_MEM_NAME_SIZE` characters (including the `NUL` termination). This function is typically used by a debugger to allow associating a name to a resource.

Arguments

`pmem` is a pointer to the memory partition that you want to name. This pointer is returned to your application when the memory partition is created (see `OSMemCreate()`).

`pname` is a pointer to an ASCII string that contains the name for the resource. The size of the string must be smaller than or equal to `OS_MEM_NAME_SIZE` characters (including the `NUL` character).

`err` a pointer to an error code and can be any of the following:

`OS_NO_ERR`	If the name of the event flag group was copied to the array pointed to by `pname`.
`OS_ERR_INVALID_PMEM`	You passed a `NULL` pointer for `pmem`.

Returned Values

none

Notes/Warnings

1. The memory partition must be created before you can use this function to set the name of the resource.

Example

```
OS_MEM *CommMem;

void Task (void *pdata)
{
    INT8U  err;

    pdata = pdata;
    for (;;) {
        OSMemNameSet(CommMem, “Comm. Buffer”, &err);
        .
        .
    }
}
```

OSMemPut()

```
INT8U OSMemPut(OS_MEM *pmem, void *pblk);
```

Chapter	*File*	*Called from*	*Code enabled by*
12	OS_MEM.C	Task or ISR	OS_MEM_EN

`OSMemPut()` returns a memory block to a memory partition. It is assumed that you return the memory block to the appropriate memory partition.

Arguments

`pmem` is a pointer to the memory-partition control block that is returned to your application from the `OSMemCreate()` call.

`pblk` is a pointer to the memory block to be returned to the memory partition.

Returned Value

`OSMemPut()` returns one of the following error codes:

`OS_NO_ERR`	if a memory block is available and returned to your application.
`OS_MEM_FULL`	if the memory partition can not accept more memory blocks. This code is surely an indication that something is wrong because you are returning more memory blocks than you obtained using `OSMemGet()`.
`OS_MEM_INVALID_PMEM`	if `pmem` is a `NULL` pointer.
`OS_MEM_INVALID_PBLK`	if `pblk` is a `NULL` pointer.

Notes/Warnings

1. Memory partitions must be created before they are used.
2. You must return a memory block to the proper memory partition.

Example

```
OS_MEM *CommMem;
INT8U  *CommMsg;

void Task (void *pdata)
{
      INT8U err;

      pdata = pdata;
      for (;;) {
         err = OSMemPut(CommMem, (void *)CommMsg);
         if (err == OS_NO_ERR) {
            .                          /* Memory block released        */
            .
         }
         .
         .
      }
}
```

OSMemQuery()

```
INT8U OSMemQuery(OS_MEM *pmem, OS_MEM_DATA *pdata);
```

Chapter	*File*	*Called from*	*Code enabled by*
12	OS_MEM.C	Task or ISR	OS_MEM_EN && OS_MEM_QUERY_EN

OSMemQuery() obtains information about a memory partition. Basically, this function returns the same information found in the OS_MEM data structure but in a new data structure called OS_MEM_DATA. OS_MEM_DATA also contains an additional field that indicates the number of memory blocks in use.

Arguments

pmem is a pointer to the memory-partition control block that is returned to your application from the OSMemCreate() call.

pdata is a pointer to a data structure of type OS_MEM_DATA, which contains the following fields

```
void   *OSAddr;     /* Points to beginning address of the memory partition
*/
void   *OSFreeList; /* Points to beginning of the free list of memory
blocks */
INT32U  OSBlkSize;  /* Size (in bytes) of each memory block
*/
INT32U  OSNBlks;    /* Total number of blocks in the partition
*/
INT32U  OSNFree;    /* Number of memory blocks free
*/
INT32U  OSNUsed;    /* Number of memory blocks used
*/
```

Returned Value

OSMemQuery() returns one of the following error codes:

OS_NO_ERR	if a memory block is available and returned to your application.
OS_MEM_INVALID_PMEM	if pmem is a NULL pointer.
OS_MEM_INVALID_PDATA	if pdata is a NULL pointer.

Notes/Warnings

1. Memory partitions must be created before they are used.

Example

```
OS_MEM      *CommMem;

void Task (void *pdata)
{
      INT8U        err;
      OS_MEM_DATA  mem_data;

      pdata = pdata;
      for (;;) {
         .
         .
         err = OSMemQuery(CommMem, &mem_data);
         .
         .
      }
}
```

OSMutexAccept()

```
INT8U OSMutexAccept(OS_EVENT *pevent, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
8	OS_MUTEX.C	Task	OS_MUTEX_EN

`OSMutexAccept()` allows you to check to see if a resource is available. Unlike `OSMutexPend()`, `OSMutexAccept()` does not suspend the calling task if the resource is not available. In other words, `OSMutexAccept()` is non-blocking.

Arguments

`pevent` is a pointer to the mutex that guards the resource. This pointer is returned to your application when the mutex is created [see `OSMutexCreate()`].

`err` is a pointer to a variable used to hold an error code. `OSMutexAccept()` sets `*err` to one of the following:

`OS_NO_ERR`	if the call is successful.
`OS_ERR_EVENT_TYPE`	if `pevent` is not pointing to a mutex.
`OS_ERR_PEVENT_NULL`	if `pevent` is a `NULL` pointer.
`OS_ERR_PEND_ISR`	if you call `OSMutexAccept()` from an ISR.

Returned Value

If the mutex is available, `OSMutexAccept()` returns 1. If the mutex is owned by another task, `OSMutexAccept()` returns 0.

Notes/Warnings

1. Mutexes must be created before they are used.
2. This function **must not** be called by an ISR.
3. If you acquire the mutex through `OSMutexAccept()`, you **must** call `OSMutexPost()` to release the mutex when you are done with the resource.

Example

```
OS_EVENT *DispMutex;

void Task (void *pdata)
{
    INT8U  err;
    INT8U  value;

    pdata = pdata;
    for (;;) {
        value = OSMutexAccept(DispMutex, &err);
        if (value == 1) {
            .                          /* Resource available, process */
            .
        } else {
            .                          /* Resource NOT available      */
            .
        }
        .
        .
    }
}
```

OSMutexCreate()

```
OS_EVENT *OSMutexCreate(INT8U prio, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
8	OS_MUTEX.C	Task or startup code	OS_MUTEX_EN

`OSMutexCreate()` is used to create and initialize a mutex. A mutex is used to gain exclusive access to a resource.

Arguments

`prio` is the priority inheritance priority (PIP) that is used when a high priority task attempts to acquire the mutex that is owned by a low priority task. In this case, the priority of the low priority task is *raised* to the PIP until the resource is released.

`err` is a pointer to a variable that is used to hold an error code. The error code can be one of the following:

`OS_NO_ERR`	if the call is successful and the mutex has been created.
`OS_ERR_CREATE_ISR`	if you attempt to create a mutex from an ISR.
`OS_PRIO_EXIST`	if a task at the specified priority inheritance priority already exists.
`OS_ERR_PEVENT_NULL`	if no more `OS_EVENT` structures are available.
`OS_PRIO_INVALID`	if you specify a priority with a higher number than `OS_LOWEST_PRIO`.

Returned Value

A pointer to the event control block allocated to the mutex. If no event control block is available, `OSMutexCreate()` returns a `NULL` pointer.

Notes/Warnings

1. Mutexes must be created before they are used.
2. You **must** make sure that `prio` has a higher priority than **any** of the tasks that use the mutex to access the resource. For example, if three tasks of priority 20, 25, and 30 are going to use the mutex, then `prio` must be a number **lower** than 20. In addition, there **must not** already be a task created at the specified priority.

Example

```
OS_EVENT *DispMutex;

void main (void)
{
    INT8U  err;

    .
    .
    OSInit();                              /* Initialize µC/OS-II
*/
    .
    .
    DispMutex = OSMutexCreate(20, &err);  /* Create Display Mutex
*/
    .
    .
    OSStart();                             /* Start Multitasking
*/
}
```

OSMutexDel()

```
OS_EVENT *OSMutexDel(OS_EVENT *pevent, INT8U opt, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
8	OS_MUTEX.C	Task	OS_MUTEX_EN and OS_MUTEX_DEL_EN

`OSMutexDel()` is used to delete a mutex. This function is dangerous to use because multiple tasks could attempt to access a deleted mutex. You should always use this function with great care. Generally speaking, before you delete a mutex, you must first delete all the tasks that can access the mutex.

Arguments

`pevent` is a pointer to the mutex. This pointer is returned to your application when the mutex is created [see `OSMutexCreate()`].

`opt` specifies whether you want to delete the mutex only if there are no pending tasks (`OS_DEL_NO_PEND`) or whether you always want to delete the mutex regardless of whether tasks are pending or not (`OS_DEL_ALWAYS`). In this case, all pending task are readied.

`err` is a pointer to a variable that is used to hold an error code. The error code can be one of the following:

`OS_NO_ERR`	if the call is successful and the mutex has been deleted.
`OS_ERR_DEL_ISR`	if you attempt to delete a mutex from an ISR.
`OS_ERR_INVALID_OPT`	if you don't specify one of the two options mentioned in the `opt` argument.
`OS_ERR_TASK_WAITING`	if one or more task are waiting on the mutex and you specify `OS_DEL_NO_PEND`.
`OS_ERR_EVENT_TYPE`	if `pevent` is not pointing to a mutex.
`OS_ERR_PEVENT_NULL`	if no more `OS_EVENT` structures are available.

Returned Value

A `NULL` pointer if the mutex is deleted or `pevent` if the mutex is not deleted. In the latter case, you need to examine the error code to determine the reason.

Notes/Warnings

1. You should use this call with care because other tasks might expect the presence of the mutex.

Example

```
OS_EVENT *DispMutex;

void Task (void *pdata)
{
    INT8U  err;

    pdata = pdata;
    while (1) {
        .
        .
        DispMutex = OSMutexDel(DispMutex, OS_DEL_ALWAYS, &err);
        if (DispMutex == (OS_EVENT *)0) {
            /* Mutex has been deleted */
        }
        .
        .
    }
}
```

OSMutexPend()

```
void OSMutexPend(OS_EVENT *pevent, INT16U timeout, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
8	OS_MUTEX.C	Task only	OS_MUTEX_EN

`OSMutexPend()` is used when a task desires to get exclusive access to a resource. If a task calls `OSMutexPend()` and the mutex is available, then `OSMutexPend()` gives the mutex to the caller and returns to its caller. Note that nothing is actually given to the caller except for the fact that if `err` is set to `OS_NO_ERR`, the caller can assume that it owns the mutex. However, if the mutex is already owned by another task, `OSMutexPend()` places the calling task in the wait list for the mutex. The task thus waits until the task that owns the mutex releases the mutex and thus the resource or until the specified timeout expires. If the mutex is signaled before the timeout expires, _C/OS-II resumes the highest priority task that is waiting for the mutex. Note that if the mutex is owned by a lower priority task, then `OSMutexPend()` raises the priority of the task that owns the mutex to the PIP, as specified when you created the mutex [see `OSMutexCreate()`].

Arguments

`pevent` is a pointer to the mutex. This pointer is returned to your application when the mutex is created [see `OSMutexCreate()`].

`timeout` is used to allow the task to resume execution if the mutex is not signaled (i.e., posted to) within the specified number of clock ticks. A timeout value of 0 indicates that the task desires to wait forever for the mutex. The maximum timeout is 65,535 clock ticks. The timeout value is not synchronized with the clock tick. The timeout count starts being decremented on the next clock tick, which could potentially occur immediately.

`err` is a pointer to a variable that is used to hold an error code. `OSMutexPend()` sets `*err` to one of the following:

`OS_NO_ERR`	if the call is successful and the mutex is available.
`OS_TIMEOUT`	if the mutex is not available within the specified timeout.
`OS_ERR_EVENT_TYPE`	if you don't pass a pointer to a mutex to `OSMutexPend()`.
`OS_ERR_PEVENT_NULL`	if `pevent` is a `NULL` pointer.
`OS_ERR_PEND_ISR`	if you attempt to acquire the mutex from an ISR.

Returned Value

none

Notes/Warnings

1. Mutexes must be created before they are used.
2. You should **not** suspend the task that owns the mutex, have the mutex owner wait on any other µC/OS-II objects (i.e., semaphore, mailbox, or queue), and delay the task that owns the mutex. In other words, your code should hurry up and release the resource as quickly as possible.

Example

```
OS_EVENT *DispMutex;

void  DispTask (void *pdata)
{
    INT8U  err;

    pdata = pdata;
    for (;;) {
        .
        .
        OSMutexPend(DispMutex, 0, &err);
        .                               /* The only way this task continues
is if _ */
        .                               /* _ the mutex is available or
signaled!    */
    }
}
```

OSMutexPost()

```
INT8U OSMutexPost(OS_EVENT *pevent);
```

Chapter	*File*	*Called from*	*Code enabled by*
8	OS_MUTEX.C	Task	OS_MUTEX_EN

A mutex is signaled (i.e., released) by calling `OSMutexPost()`. You call this function only if you acquire the mutex by first calling either `OSMutexAccept()` or `OSMutexPend()`. If the priority of the task that owns the mutex has been raised when a higher priority task attempts to acquire the mutex, the original task priority of the task is restored. If one or more tasks are waiting for the mutex, the mutex is given to the highest priority task waiting on the mutex. The scheduler is then called to determine if the awakened task is now the highest priority task ready to run, and if so, a context switch is done to run the readied task. If no task is waiting for the mutex, the mutex value is simply set to available (`0xFF`).

Arguments

`pevent` is a pointer to the mutex. This pointer is returned to your application when the mutex is created [see `OSMutexCreate()`].

Returned Value

`OSMutexPost()` returns one of these error codes:

`OS_NO_ERR`	if the call is successful and the mutex is released.
`OS_ERR_EVENT_TYPE`	if you don't pass a pointer to a mutex to `OSMutexPost()`.
`OS_ERR_PEVENT_NULL`	if `pevent` is a `NULL` pointer.
`OS_ERR_POST_ISR`	if you attempt to call `OSMutexPost()` from an ISR.
`OS_ERR_NOT_MUTEX_OWNER`	if the task posting (i.e., signaling the mutex) doesn't actually own the mutex.

Notes/Warnings

1. Mutexes must be created before they are used.
2. You cannot call this function from an ISR.

Example

```
OS_EVENT  *DispMutex;

void  TaskX (void *pdata)
{
    INT8U  err;

    pdata = pdata;
    for (;;) {
        .
        .
        err = OSMutexPost(DispMutex);
        switch (err) {
           case OS_NO_ERR: /* Mutex signaled       */
                .
                .
                break;

           case OS_ERR_EVENT_TYPE:
                .
                .
                break;

           case OS_ERR_PEVENT_NULL:
                .
                .
                break;

           case OS_ERR_POST_ISR:
                .
                .
                break;

        }
        .
        .
    }
}
```

OSMutexQuery()

```
INT8U OSMutexQuery(OS_EVENT *pevent, OS_MUTEX_DATA *pdata);
```

Chapter	*File*	*Called from*	*Code enabled by*
8	OS_MUTEX.C	Task	OS_MUTEX_EN && OS_MUTEX_QUERY_EN

OSMutexQuery() is used to obtain run-time information about a mutex. Your application must allocate an OS_MUTEX_DATA data structure that is used to receive data from the event control block of the mutex. OSMutexQuery() allows you to determine whether any task is waiting on the mutex, how many tasks are waiting (by counting the number of 1s) in the .OSEventTbl[] field, obtain the PIP, and determine whether the mutex is available (1) or not (0). Note that the size of .OSEventTbl[] is established by the #define constant OS_EVENT_TBL_SIZE (see uCOS_II.H).

Arguments

pevent is a pointer to the mutex. This pointer is returned to your application when the mutex is created [see OSMutexCreate()].

pdata is a pointer to a data structure of type OS_MUTEX_DATA, which contains the following fields

```
INT8U  OSMutexPIP;    /* The PIP of the mutex                          */
INT8U  OSOwnerPrio;   /* The priority of the mutex owner               */
INT8U  OSValue;       /* The current mutex value, 1 means available,   */
                      /* 0 means unavailable                           */
INT8U  OSEventGrp;    /* Copy of the mutex wait list                   */
INT8U  OSEventTbl[OS_EVENT_TBL_SIZE];
```

Returned Value

OSMutexQuery() returns one of these error codes:

OS_NO_ERR	if the call is successful.
OS_ERR_EVENT_TYPE	if you don't pass a pointer to a mutex to OSMutexQuery().
OS_ERR_PEVENT_NULL	if pevent is a NULL pointer.
OS_ERR_QUERY_ISR	if you attempt to call OSMutexQuery() from an ISR.

Notes/Warnings

1. Mutexes must be created before they are used.
2. You cannot call this function from an ISR.

Example

In this example, we check the contents of the mutex to determine the highest priority task that is waiting for it.

```
OS_EVENT *DispMutex;

void Task (void *pdata)
{
    OS_MUTEX_DATA mutex_data;
    INT8U         err;
    INT8U         highest;       /* Highest priority task waiting on mutex
*/
    INT8U         x;
    INT8U         y;

    for (;;) {
        .
        .
        err = OSMutexQuery(DispMutex, &mutex_data);
        if (err == OS_NO_ERR) {
            if (mutex_data.OSEventGrp != 0x00) {
                y       = OSUnMapTbl[mutex_data.OSEventGrp];
                x       = OSUnMapTbl[mutex_data.OSEventTbl[y]];
                highest = (y << 3) + x;
                .
                .
            }
        }
        .
        .
    }
}
```

OSQAccept()

```
void *OSQAccept(OS_EVENT *pevent, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
11	OS_Q.C	Task or ISR	OS_Q_EN

`OSQAccept()` checks to see if a message is available in the desired message queue. Unlike `OSQPend()`, `OSQAccept()` does not suspend the calling task if a message is not available. In other words, `OSQAccept()` is non-blocking. If a message is available, it is extracted from the queue and returned to your application. This call is typically used by ISRs because an ISR is not allowed to wait for messages at a queue.

Arguments

`pevent` is a pointer to the message queue from which the message is received. This pointer is returned to your application when the message queue is created [see `OSQCreate()`].

`err` is a pointer to a variable that is used to hold an error code. `OSQAccept()` sets `*err` to one of the following:

`OS_NO_ERR`	if the call is successful and the mutex is available.
`OS_ERR_EVENT_TYPE`	if you don't pass a pointer to a queue to `OSQAccept()`.
`OS_ERR_PEVENT_NULL`	if `pevent` is a `NULL` pointer.
`OS_Q_EMPTY`	if the queue doesn't contain any messages.

Returned Value

A pointer to the message if one is available; `NULL` if the message queue does not contain a message or the message received is a `NULL` pointer. If a message was available in the queue, it will be removed before `OSQAccept()` returns.

Notes/Warnings

1. Message queues must be created before they are used.
2. The API (Application Programming Interface) has changed for this function in V2.60 becausee you can now post `NULL` pointers to queues. Specifically, the `err` argument has been added to the call.

Example

```
OS_EVENT *CommQ;

void Task (void *pdata)
{
      void *msg;

      pdata = pdata;
      for (;;) {
         msg = OSQAccept(CommQ);       /* Check queue for a message   */
         if (msg != (void *)0) {
            .                          /* Message received, process   */
            .
         } else {
            .                          /* Message not received, do .. */
            .                          /* .. something else           */
         }
         .
         .
      }
}
```

OSQCreate()

```
OS_EVENT *OSQCreate(void **start, INT8U size);
```

Chapter	*File*	*Called from*	*Code enabled by*
11	OS_Q.C	Task or startup code	OS_Q_EN

`OSQCreate()` creates a message queue. A message queue allows tasks or ISRs to send pointer-sized variables (messages) to one or more tasks. The meaning of the messages sent are application specific.

Arguments

`start` is the base address of the message storage area. A message storage area is declared as an array of pointers to voids.

`size` is the size (in number of entries) of the message storage area.

Returned Value

`OSQCreate()` returns a pointer to the event control block allocated to the queue. If no event control block is available, `OSQCreate()` returns a `NULL` pointer.

Notes/Warnings

1. Queues must be created before they are used.

Example

```
OS_EVENT *CommQ;
void     *CommMsg[10];

void main (void)
{
       OSInit();                                    /* Initialize µC/OS-II
*/
       .
       .
       CommQ = OSQCreate(&CommMsg[0], 10);          /* Create COMM Q
*/
       .
       .
       OSStart();                                   /* Start Multitasking
*/
}
```

OSQDel()

```
OS_EVENT *OSQDel(OS_EVENT *pevent, INT8U opt, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
11	OS_Q.C	Task	OS_Q_EN and OS_Q_DEL_EN

OSQDel() is used to delete a message queue. This function is dangerous to use because multiple tasks could attempt to access a deleted queue. You should always use this function with great care. Generally speaking, before you delete a queue, you must first delete all the tasks that can access the queue.

Arguments

pevent is a pointer to the queue. This pointer is returned to your application when the queue is created [see OSQCreate()].

opt specifies whether you want to delete the queue only if there are no pending tasks (OS_DEL_NO_PEND) or whether you always want to delete the queue regardless of whether tasks are pending or not (OS_DEL_ALWAYS). In this case, all pending task are readied.

err is a pointer to a variable that is used to hold an error code. The error code can be one of the following:

OS_NO_ERR	if the call is successful and the queue has been deleted.
OS_ERR_DEL_ISR	if you attempt to delete the queue from an ISR.
OS_ERR_INVALID_OPT	if you don't specify one of the two options mentioned in the opt argument.
OS_ERR_TASK_WAITING	if one or more tasks are waiting for messages at the message queue.
OS_ERR_EVENT_TYPE	if pevent is not pointing to a queue.
OS_ERR_PEVENT_NULL	if no more OS_EVENT structures are available.

Returned Value

A NULL pointer if the queue is deleted or pevent if the queue is not deleted. In the latter case, you need to examine the error code to determine the reason.

Notes/Warnings

1. You should use this call with care because other tasks might expect the presence of the queue.
2. Interrupts are disabled when pended tasks are readied, which means that interrupt latency depends on the number of tasks that are waiting on the queue.

Example

```
OS_EVENT *DispQ;

void Task (void *pdata)
{
    INT8U  err;

    pdata = pdata;
    while (1) {
        .
        .
        DispQ = OSQDel(DispQ, OS_DEL_ALWAYS, &err);
        if (DispQ == (OS_EVENT *)0) {
            /* Queue has been deleted */
        }
        .
        .
    }
}
```

OSQFlush()

```
INT8U *OSQFlush(OS_EVENT *pevent);
```

Chapter	*File*	*Called from*	*Code enabled by*
11	OS_Q.C	Task or ISR	OS_Q_EN && OS_Q_FLUSH_EN

`OSQFlush()` empties the contents of the message queue and eliminates all the messages sent to the queue. This function takes the same amount of time to execute regardless of whether tasks are waiting on the queue (and thus no messages are present) or the queue contains one or more messages.

Arguments

`pevent` is a pointer to the message queue. This pointer is returned to your application when the message queue is created [see `OSQCreate()`].

Returned Value

`OSQFlush()` returns one of the following codes:

`OS_NO_ERR`	if the message queue is flushed.
`OS_ERR_EVENT_TYPE`	if you attempt to flush an object other than a message queue.
`OS_ERR_PEVENT_NULL`	if `pevent` is a `NULL` pointer.

Notes/Warnings

1. Queues must be created before they are used.
2. You should use this function with great care because, when to flush the queue, you LOOSE the references to what the queue entries are pointing to and thus, you could cause 'memory leaks'. In other words, the data you are pointing to that's being referenced by the queue entries should, most likely, need to be de-allocated (i.e. freed). To flush a queue that contains entries, you should instead repeateadly use `OSQAccept()`.

Example

```
OS_EVENT *CommQ;

void main (void)
{
       INT8U err;

       OSInit();                             /* Initialize µC/OS-II   */
       .
       .
       err = OSQFlush(CommQ);
       .
       .
       OSStart();                            /* Start Multitasking    */
}
```

OSQPend()

```
void *OSQPend(OS_EVENT *pevent, INT16U timeout, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
11	OS_Q.C	Task only	OS_Q_EN

OSQPend() is used when a task wants to receive messages from a queue. The messages are sent to the task either by an ISR or by another task. The messages received are pointer-sized variables, and their use is application specific. If at least one message is present at the queue when OSQPend() is called, the message is retrieved and returned to the caller. If no message is present at the queue, OSQPend() suspends the current task until either a message is received or a user-specified timeout expires. If a message is sent to the queue and multiple tasks are waiting for such a message, then µC/OS-II resumes the highest priority task that is waiting. A pended task that has been suspended with OSTaskSuspend() can receive a message. However, the task remains suspended until it is resumed by calling OSTaskResume().

Arguments

pevent is a pointer to the queue from which the messages are received. This pointer is returned to your application when the queue is created [see OSQCreate()].

timeout allows the task to resume execution if a message is not received from the mailbox within the specified number of clock ticks. A timeout value of 0 indicates that the task wants to wait forever for the message. The maximum timeout is 65,535 clock ticks. The timeout value is not synchronized with the clock tick. The timeout count starts decrementing on the next clock tick, which could potentially occur immediately.

err is a pointer to a variable used to hold an error code. OSQPend() sets *err to one of the following:

OS_NO_ERR	if a message is received.
OS_TIMEOUT	if a message is not received within the specified timeout.
OS_ERR_EVENT_TYPE	if pevent is not pointing to a message queue.
OS_ERR_PEVENT_NULL	if pevent is a NULL pointer.
OS_ERR_PEND_ISR	if you call this function from an ISR and µC/OS-II has to suspend it. In general, you should not call OSQPend() from an ISR. _C/OS-II checks for this situation anyway.

Returned Value

OSQPend() returns a message sent by either a task or an ISR, and *err is set to OS_NO_ERR. If a timeout occurs, OSQPend() returns a NULL pointer and sets *err to OS_TIMEOUT.

Notes/Warnings

1. Queues must be created before they are used.
2. You should not call OSQPend() from an ISR.
3. OSQPend() was changed in V2.60 to allow it to receive NULL pointer messages.

Example

```
OS_EVENT *CommQ;

void CommTask(void *data)
{
      INT8U  err;
      void  *msg;

      pdata = pdata;
      for (;;) {
         .
         .
         msg = OSQPend(CommQ, 100, &err);
         if (err == OS_NO_ERR) {
            .
            .         /* Message received within 100 ticks!         */
            .
         } else {
            .
            .         /* Message not received, must have timed out  */
            .
         }
         .
         .
      }
}
```

OSQPost()

```
INT8U OSQPost(OS_EVENT *pevent, void *msg);
```

Chapter	*File*	*Called from*	*Code enabled by*
11	OS_Q.C	Task or ISR	OS_Q_EN && OS_Q_POST_EN

OSQPost() sends a message to a task through a queue. A message is a pointer-sized variable, and its use is application specific. If the message queue is full, an error code is returned to the caller. In this case, OSQPost() immediately returns to its caller, and the message is not placed in the queue. If any task is waiting for a message at the queue, the highest priority task receives the message. If the task waiting for the message has a higher priority than the task sending the message, the higher priority task resumes, and the task sending the message is suspended; that is, a context switch occurs. Message queues are first-in first-out (FIFO), which means that the first message sent is the first message received.

Arguments

pevent is a pointer to the queue into which the message is deposited. This pointer is returned to your application when the queue is created [see OSQCreate()].

msg is the actual message sent to the task. msg is a pointer-sized variable and is application specific. As of V2.60, you are allowed to post a NULL pointer.

Returned Value

OSQPost() returns one of these error codes:

OS_NO_ERR	if the message is deposited in the queue.
OS_Q_FULL	if the queue is already full.
OS_ERR_EVENT_TYPE	if pevent is not pointing to a message queue.
OS_ERR_PEVENT_NULL	if pevent is a NULL pointer.

Notes/Warnings

1. Queues must be created before they are used.
2. As of V2.60, you are now allowed to post a NULL pointer. It is up to you're application to check the err variable accordingly.

Example

```
OS_EVENT *CommQ;
INT8U     CommRxBuf[100];

void CommTaskRx (void *pdata)
{
      INT8U  err;

      pdata = pdata;
      for (;;) {
         .
         .
         err = OSQPost(CommQ, (void *)&CommRxBuf[0]);
         switch (err) {
             case OS_NO_ERR:
                  /* Message was deposited into queue    */
                  break;

             case OS_Q_FULL:
                  /* Queue is full                       */
                  Break;
            .
         }
         .
         .
      }
}
```

OSQPostFront()

```
INT8U OSQPostFront(OS_EVENT *pevent, void *msg);
```

Chapter	*File*	*Called from*	*Code enabled by*
11	OS_Q.C	Task or ISR	OS_Q_EN && OS_Q_POST_FRONT_EN

`OSQPostFront()` sends a message to a task through a queue. `OSQPostFront()` behaves very much like `OSQPost()`, except that the message is inserted at the front of the queue. This means that `OSQPostFront()` makes the message queue behave like a last-in first-out (LIFO) queue instead of a first-in first-out (FIFO) queue. The message is a pointer-sized variable, and its use is application specific. If the message queue is full, an error code is returned to the caller. `OSQPostFront()` immediately returns to its caller, and the message is not placed in the queue. If any tasks are waiting for a message at the queue, the highest priority task receives the message. If the task waiting for the message has a higher priority than the task sending the message, the higher priority task is resumed, and the task sending the message is suspended; that is, a context switch occurs.

Arguments

`pevent` is a pointer to the queue into which the message is deposited. This pointer is returned to your application when the queue is created [see `OSQCreate()`].

`msg` is the actual message sent to the task. `msg` is a pointer-sized variable and is application specific. As of V2.60, you are allowed to post a `NULL` pointer.

Returned Value

`OSQPostFront()` returns one of these error codes:

`OS_NO_ERR`	if the message is deposited in the queue.
`OS_Q_FULL`	if the queue is already full.
`OS_ERR_EVENT_TYPE`	if `pevent` is not pointing to a message queue.
`OS_ERR_PEVENT_NULL`	if `pevent` is a `NULL` pointer.

Notes/Warnings

1. Queues must be created before they are used.
2. As of V2.60, you are now allowed to post a `NULL` pointer. It is up to you're application to check the `err` variable accordingly.

Example

```
OS_EVENT *CommQ;
INT8U     CommRxBuf[100];

void CommTaskRx (void *pdata)
{
      INT8U  err;

      pdata = pdata;
      for (;;) {
         .
         .
         err = OSQPostFront(CommQ, (void *)&CommRxBuf[0]);
         switch (err) {
             case OS_NO_ERR:
                  /* Message was deposited into queue    */
                  break;

             case OS_Q_FULL:
                  /* Queue is full                       */
                  break;
            .
         }
         .
         .
      }
}
```

OSQPostOpt()

```
INT8U OSQPostOpt(OS_EVENT *pevent, void *msg, INT8U opt);
```

Chapter	*File*	*Called from*	*Code enabled by*
11	OS_Q.C	Task or ISR	OS_Q_EN && OS_Q_POST_OPT_EN

OSQPostOpt() is used to send a message to a task through a queue. A message is a pointer-sized variable, and its use is application specific. If the message queue is full, an error code is returned indicating that the queue is full. OSQPostOpt() then immediately returns to its caller, and the message is not placed in the queue. If any task is waiting for a message at the queue, OSQPostOpt() allows you to either post the message to the highest priority task waiting at the queue (opt set to OS_POST_OPT_NONE) or to all tasks waiting at the queue (opt is set to OS_POST_OPT_BROADCAST). In either case, scheduling occurs, and, if any of the tasks that receive the message have a higher priority than the task that is posting the message, then the higher priority task is resumed, and the sending task is suspended. In other words, a context switch occurs.

OSQPostOpt() emulates both OSQPost() and OSQPostFront() and also allows you to post a message to **multiple** tasks. In other words, it allows the message posted to be broadcast to **all** tasks waiting on the queue. OSQPostOpt() can actually replace OSQPost() and OSQPostFront() because you specify the mode of operation via an option argument, opt. Doing this allows you to reduce the amount of code space needed by µC/OS-II.

Arguments

pevent is a pointer to the queue. This pointer is returned to your application when the queue is created [see OSQCreate()].

msg is the actual message sent to the task(s). msg is a pointer-sized variable, and what msg points to is application specific. As of V2.60, you are now allowed to post a NULL pointer.

opt determines the type of POST performed:

OS_POST_OPT_NONE	POST to a single waiting task [identical to OSQPost()].
OS_POST_OPT_BROADCAST	POST to **all** tasks waiting on the queue.
OS_POST_OPT_FRONT	POST as LIFO [simulates OSQPostFront()].

Below is a list of **all** the possible combination of these flags:

OS_POST_OPT_NONE	is identical to OSQPost()
OS_POST_OPT_FRONT	is identical to OSQPostFront()
OS_POST_OPT_BROADCAST	is identical to OSQPost() but broadcasts msg to **all** waiting tasks
OS_POST_OPT_FRONT + OS_POST_OPT_BROADCAST	is identical to OSQPostFront() except that broadcasts msg to **all** waiting tasks.

Returned Value

err is a pointer to a variable that is used to hold an error code. The error code can be one of the following:

OS_NO_ERR	if the call is successful and the message has been sent.
OS_Q_FULL	if the queue can no longer accept messages because it is full.
OS_ERR_EVENT_TYPE	if pevent is not pointing to a mailbox.
OS_ERR_PEVENT_NULL	if pevent is a NULL pointer.

Notes/Warnings

1. Queues must be created before they are used.
2. If you need to use this function and want to reduce code space, you can disable code generation of `OSQPost()` (set `OS_Q_POST_EN` to 0 in `OS_CFG.H`) and `OSQPostFront()` (set `OS_Q_POST_FRONT_EN` to 0 in `OS_CFG.H`) because `OSQPostOpt()` can emulate these two functions.
3. The execution time of `OSQPostOpt()` depends on the number of tasks waiting on the queue if you set `opt` to `OS_POST_OPT_BROADCAST`.

Example

```
OS_EVENT *CommQ;
INT8U     CommRxBuf[100];

void CommRxTask (void *pdata)
{
    INT8U  err;

    pdata = pdata;
    for (;;) {
        .
        .
        err = OSQPostOpt(CommQ, (void *)&CommRxBuf[0],
OS_POST_OPT_BROADCAST);
        .
        .
    }
}
```

OSQQuery()

```
INT8U OSQQuery(OS_EVENT *pevent, OS_Q_DATA *pdata);
```

Chapter	*File*	*Called from*	*Code enabled by*
11	OS_Q.C	Task or ISR	OS_Q_EN && OS_QUERY_EN

OSQQuery() obtains information about a message queue. Your application must allocate an OS_Q_DATA data structure used to receive data from the event control block of the message queue. OSQQuery() allows you to determine whether any tasks are waiting for messages at the queue, how many tasks are waiting (by counting the number of 1s in the .OSEventTbl[] field), how many messages are in the queue, and what the message queue size is. OSQQuery() also obtains the next message that is returned if the queue is not empty. Note that the size of .OSEventTbl[] is established by the #define constant OS_EVENT_TBL_SIZE (see uCOS_II.H).

Arguments

pevent is a pointer to the message queue. This pointer is returned to your application when the queue is created [see OSQCreate()].

pdata is a pointer to a data structure of type OS_Q_DATA, which contains the following fields

```
void  *OSMsg;                   /* Next message if one available
*/
INT16U OSNMsgs;                 /* Number of messages in the queue
*/
INT16U OSQSize;                 /* Size of the message queue
*/
INT8U  OSEventTbl[OS_EVENT_TBL_SIZE];      /* Message queue wait list
*/
INT8U  OSEventGrp;
```

Returned Value

OSQQuery() returns one of these error codes:

OS_NO_ERR	if the call is successful.
OS_ERR_EVENT_TYPE	if you don't pass a pointer to a message queue.
OS_ERR_PEVENT_NULL	if pevent is a NULL pointer.

Notes/Warnings

1. Message queues must be created before they are used.

Example

```
OS_EVENT *CommQ;

void Task (void *pdata)
{
      OS_Q_DATA qdata;
      INT8U     err;

      pdata = pdata;
      for (;;) {
         .
         .
         err = OSQQuery(CommQ, &qdata);
         if (err == OS_NO_ERR) {
           .   /* 'qdata' can be examined! */
         }
         .
         .
      }
}
```

OSSchedLock()

```
void OSSchedLock(void);
```

Chapter	*File*	*Called from*	*Code enabled by*
3	OS_CORE.C	Task or ISR	OS_SCHED_LOCK_EN

`OSSchedLock()` prevents task rescheduling until its counterpart, `OSSchedUnlock()`, is called. The task that calls `OSSchedLock()` keeps control of the CPU even though other higher priority tasks are ready to run. However, interrupts are still recognized and serviced (assuming interrupts are enabled). `OSSchedLock()` and `OSSchedUnlock()` must be used in pairs. µC/OS-II allows `OSSchedLock()` to be nested up to 255 levels deep. Scheduling is enabled when an equal number of `OSSchedUnlock()` calls have been made.

Arguments

none

Returned Value

none

Notes/Warnings

1. After calling `OSSchedLock()`, your application must not make system calls that suspend execution of the current task; that is, your application cannot call `OSTimeDly()`, `OSTimeDlyHMSM()`, `OSFlagPend()`, `OSSemPend()`, `OSMutexPend()`, `OSMboxPend()`, or `OSQPend()`. Because the scheduler is locked out, no other task is allowed to run, and your system will lock up.

Example

```
void TaskX (void *pdata)
{
      pdata = pdata;
      for (;;) {
         .
         OSSchedLock();         /* Prevent other tasks to run         */
         .
         .                      /* Code protected from context switch */
         .
         OSSchedUnlock();       /* Enable other tasks to run          */
         .
      }
}
```

OSSchedUnlock()

```
void OSSchedUnlock(void);
```

Chapter	*File*	*Called from*	*Code enabled by*
3	OS_CORE.C	Task or ISR	OS_SCHED_LOCK_EN

`OSSchedUnlock()` re-enables task scheduling whenever it is paired with `OSSchedLock()`.

Arguments

none

Returned Value

none

Notes/Warnings

1. After calling `OSSchedLock()`, your application must not make system calls that suspend execution of the current task; that is, your application cannot call `OSTimeDly()`, `OSTimeDlyHMSM()`, `OSFlagPend()`, `OSSemPend()`, `OSMutexPend()`, `OSMboxPend()`, or `OSQPend()`. Because the scheduler is locked out, no other task is allowed to run, and your system will lock up.

Example

```
void TaskX (void *pdata)
{
      pdata = pdata;
      for (;;) {
         .
         OSSchedLock();     /* Prevent other tasks to run         */
         .
         .                  /* Code protected from context switch */
         .
         OSSchedUnlock();   /* Enable other tasks to run          */
         .
      }
}
```

OSSemAccept()

```
INT16U OSSemAccept(OS_EVENT *pevent);
```

Chapter	*File*	*Called from*	*Code enabled by*
7	OS_SEM.C	Task or ISR	OS_SEM_EN && OS_SEM_ACCEPT_EN

`OSSemAccept()` checks to see if a resource is available or an event has occurred. Unlike `OSSemPend()`, `OSSemAccept()` does not suspend the calling task if the resource is not available. In other words, `OSSemAccept()` is non-blocking. Use `OSSemAccept()` from an ISR to obtain the semaphore.

Arguments

`pevent` is a pointer to the semaphore that guards the resource. This pointer is returned to your application when the semaphore is created [see `OSSemCreate()`].

Returned Value

When `OSSemAccept()` is called and the semaphore value is greater than 0, the semaphore value is decremented, and the value of the semaphore before the decrement is returned to your application. If the semaphore value is 0 when `OSSemAccept()` is called, the resource is not available, and 0 is returned to your application.

Notes/Warnings

1. Semaphores must be created before they are used.

Example

```
OS_EVENT *DispSem;

void Task (void *pdata)
{
      INT16U value;

      pdata = pdata;
      for (;;) {
         value = OSSemAccept(DispSem);          /* Check resource
availability */
         if (value > 0) {
            .                                   /* Resource available,
process */
            .
         }
         .
         .
      }
}
```

OSSemCreate()

```
OS_EVENT *OSSemCreate(INT16U value);
```

Chapter	*File*	*Called from*	*Code enabled by*
7	OS_SEM.C	Task or startup code	OS_SEM_EN

`OSSemCreate()` creates and initializes a semaphore. A semaphore

- allows a task to synchronize with either an ISR or a task (you initialize the semaphore to 0),
- gains exclusive access to a resource (you initialize the semaphore to a value greater than 0), and
- signals the occurrence of an event (you initialize the semaphore to 0).

Arguments

`value` is the initial value of the semaphore and can be between 0 and 65,535. A value of 0 indicates that a resource is not available or an event has not occurred.

Returned Value

`OSSemCreate()` returns a pointer to the event control block allocated to the semaphore. If no event control block is available, `OSSemCreate()` returns a `NULL` pointer.

Notes/Warnings

1. Semaphores must be created before they are used.

Example

```
OS_EVENT *DispSem;

void main (void)
{
      .
      .
      OSInit();                     /* Initialize µC/OS-II             */
      .
      .
      DispSem = OSSemCreate(1);     /* Create Display Semaphore        */
      .
      .
      OSStart();                    /* Start Multitasking              */
}
```

OSSemDel()

```
OS_EVENT *OSSemDel(OS_EVENT *pevent, INT8U opt, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
7	OS_SEM.C	Task	OS_SEM_EN and OS_SEM_DEL_EN

OSSemDel() is used to delete a semaphore. This function is dangerous to use because multiple tasks could attempt to access a deleted semaphore. You should always use this function with great care. Generally speaking, before you delete a semaphore, you must first delete all the tasks that can access the semaphore.

Arguments

pevent is a pointer to the semaphore. This pointer is returned to your application when the semaphore is created [see OSSemCreate()].

opt specifies whether you want to delete the semaphore only if there are no pending tasks (OS_DEL_NO_PEND) or whether you always want to delete the semaphore regardless of whether tasks are pending or not (OS_DEL_ALWAYS). In this case, all pending task are readied.

err is a pointer to a variable that is used to hold an error code. The error code can be one of the following:

OS_NO_ERR	if the call is successful and the semaphore has been deleted.
OS_ERR_DEL_ISR	if you attempt to delete the semaphore from an ISR.
OS_ERR_INVALID_OPT	if you don't specify one of the two options mentioned in the opt argument.
OS_ERR_TASK_WAITING	if one or more tasks are waiting on the semaphore.
OS_ERR_EVENT_TYPE	if pevent is not pointing to a semaphore.
OS_ERR_PEVENT_NULL	if no more OS_EVENT structures are available.

Returned Value

A NULL pointer if the semaphore is deleted or pevent if the semaphore is not deleted. In the latter case, you need to examine the error code to determine the reason.

Notes/Warnings

1. You should use this call with care because other tasks might expect the presence of the semaphore.
2. Interrupts are disabled when pended tasks are readied, which means that interrupt latency depends on the number of tasks that are waiting on the semaphore.

Example

```
OS_EVENT *DispSem;

void Task (void *pdata)
{
    INT8U  err;

    pdata = pdata;
    while (1) {
        .
        .
        DispSem = OSSemDel(DispSem, OS_DEL_ALWAYS, &err);
        if (DispSem == (OS_EVENT *)0) {
            /* Semaphore has been deleted */
        }
        .
        .
    }
}
```

OSSemPend()

```
void OSSemPend(OS_EVENT *pevent, INT16U timeout, INT8U *err);
```

Chapter	*File*	*Called from*	*Code enabled by*
7	OS_SEM.C	Task only	OS_SEM_EN

`OSSemPend()` is used when a task wants exclusive access to a resource, needs to synchronize its activities with an ISR or a task, or is waiting until an event occurs. If a task calls `OSSemPend()` and the value of the semaphore is greater than 0, `OSSemPend()` decrements the semaphore and returns to its caller. However, if the value of the semaphore is 0, `OSSemPend()` places the calling task in the waiting list for the semaphore. The task waits until a task or an ISR signals the semaphore or the specified timeout expires. If the semaphore is signaled before the timeout expires, µC/OS-II resumes the highest priority task waiting for the semaphore. A pended task that has been suspended with `OSTaskSuspend()` can obtain the semaphore. However, the task remains suspended until it is resumed by calling `OSTaskResume()`.

Arguments

`pevent` is a pointer to the semaphore. This pointer is returned to your application when the semaphore is created [see `OSSemCreate()`].

`timeout` allows the task to resume execution if a message is not received from the mailbox within the specified number of clock ticks. A timeout value of 0 indicates that the task waits forever for the message. The maximum timeout is 65,535 clock ticks. The timeout value is not synchronized with the clock tick. The timeout count begins decrementing on the next clock tick, which could potentially occur immediately.

`err` is a pointer to a variable used to hold an error code. `OSSemPend()` sets `*err` to one of the following:

`OS_NO_ERR`	if the semaphore is available.
`OS_TIMEOUT`	if the semaphore is not signaled within the specified timeout.
`OS_ERR_EVENT_TYPE`	if `pevent` is not pointing to a semaphore.
`OS_ERR_PEND_ISR`	if you called this function from an ISR and µC/OS-II has to suspend it. You should not call `OSSemPend()` from an ISR. µC/OS-II checks for this situation.
`OS_ERR_PEVENT_NULL`	if `pevent` is a `NULL` pointer.

Returned Value

none

Notes/Warnings

1. Semaphores must be created before they are used.

Example

```
OS_EVENT *DispSem;

void DispTask (void *pdata)
{
      INT8U  err;

      pdata = pdata;
      for (;;) {
         .
         .
         OSSemPend(DispSem, 0, &err);
         .              /* The only way this task continues is if _ */
         .              /* _ the semaphore is signaled!             */
      }
}
```

OSSemPost()

```
INT8U OSSemPost(OS_EVENT *pevent);
```

Chapter	*File*	*Called from*	*Code enabled by*
7	OS_SEM.C	Task or ISR	OS_SEM_EN

A semaphore is signaled by calling `OSSemPost()`. If the semaphore value is 0 or more, it is incremented, and `OSSemPost()` returns to its caller. If tasks are waiting for the semaphore to be signaled, `OSSemPost()` removes the highest priority task pending for the semaphore from the waiting list and makes this task ready to run. The scheduler is then called to determine if the awakened task is now the highest priority task ready to run.

Arguments

`pevent` is a pointer to the semaphore. This pointer is returned to your application when the semaphore is created [see `OSSemCreate()`].

Returned Value

`OSSemPost()` returns one of these error codes:

`OS_NO_ERR`	if the semaphore is signaled successfully.
`OS_SEM_OVF`	if the semaphore count overflows.
`OS_ERR_EVENT_TYPE`	if `pevent` is not pointing to a semaphore.
`OS_ERR_PEVENT_NULL`	if `pevent` is a `NULL` pointer.

Notes/Warnings

1. Semaphores must be created before they are used.

Example

```
OS_EVENT *DispSem;

void TaskX (void *pdata)
{
      INT8U  err;

      pdata = pdata;
      for (;;) {
         .
         .
         err = OSSemPost(DispSem);
         switch (err) {
             case OS_NO_ERR:
                  /* Semaphore signaled       */
                  break;

             case OS_SEM_OVF:
                  /* Semaphore has overflowed */
                  break;
            .
            .
         }
         .
         .
      }
}
```

OSSemQuery()

```
INT8U OSSemQuery(OS_EVENT *pevent, OS_SEM_DATA *pdata);
```

Chapter	*File*	*Called from*	*Code enabled by*
7	OS_SEM.C	Task or ISR	OS_SEM_EN && OS_SEM_QUERY_EN

OSSemQuery() obtains information about a semaphore. Your application must allocate an OS_SEM_DATA data structure used to receive data from the event control block of the semaphore. OSSemQuery() allows you to determine whether any tasks are waiting on the semaphore and how many tasks are waiting (by counting the number of 1s in the .OSEventTbl[] field) and obtains the semaphore count. Note that the size of .OSEventTbl[] is established by the #define constant OS_EVENT_TBL_SIZE (see uCOS_II.H).

Arguments

pevent is a pointer to the semaphore. This pointer is returned to your application when the semaphore is created [see OSSemCreate()].

pdata is a pointer to a data structure of type OS_SEM_DATA, which contains the following fields

```
INT16U OSCnt;                                    /* Current semaphore count
*/
INT8U  OSEventTbl[OS_EVENT_TBL_SIZE];            /* Semaphore wait list
*/
INT8U  OSEventGrp;
```

Returned Value

OSSemQuery() returns one of these error codes:

OS_NO_ERR	if the call is successful.
OS_ERR_EVENT_TYPE	if you don't pass a pointer to a semaphore.
OS_ERR_PEVENT_NULL	if pevent is is a NULL pointer.

Notes/Warnings

1. Semaphores must be created before they are used.

Example

In this example, the contents of the semaphore is checked to determine the highest priority task waiting at the time the function call was made.

```
OS_EVENT *DispSem;

void Task (void *pdata)
{
      OS_SEM_DATA sem_data;
      INT8U       err;
      INT8U       highest; /* Highest priority task waiting on sem. */
      INT8U       x;
      INT8U       y;

      pdata = pdata;
      for (;;) {
         .
         .
         err = OSSemQuery(DispSem, &sem_data);
         if (err == OS_NO_ERR) {
            if (sem_data.OSEventGrp != 0x00) {
                y       = OSUnMapTbl[sem_data.OSEventGrp];
                x       = OSUnMapTbl[sem_data.OSEventTbl[y]];
                highest = (y << 3) + x;
                .
                .
            }
         }
         .
         .
      }
}
```

OSStart()

```
void OSStart(void);
```

Chapter	*File*	*Called from*	*Code enabled by*
3	OS_CORE.C	Startup code only	N/A

`OSStart()` starts multitasking under µC/OS-II. This function is typically called from your startup code but after you call `OSInit()`.

Arguments

none

Returned Value

none

Notes/Warnings

1. `OSInit()` must be called prior to calling `OSStart()`. `OSStart()` should only be called once by your application code. If you do call `OSStart()` more than once, it does not do anything on the second and subsequent calls.

Example

```
void main (void)
{
    .                                   /* User Code            */
    .
    OSInit();                           /* Initialize µC/OS-II  */
    .                                   /* User Code            */
    .
    OSStart();                          /* Start Multitasking   */
    /* Any code here should NEVER be executed! */
}
```

OSStatInit()

```
void OSStatInit(void);
```

Chapter	*File*	*Called from*	*Code enabled by*
3	OS_CORE.C	Startup code only	OS_TASK_STAT_EN && OS_TASK_CREATE_EXT_EN

`OSStatInit()` determines the maximum value that a 32-bit counter can reach when no other task is executing. This function must be called when only one task is created in your application and when multitasking has started; that is, this function must be called from the first and, only, task created.

Arguments

none

Returned Value

none

Notes/Warnings

none

Example

```
void FirstAndOnlyTask (void *pdata)
{
      .
      .
      OSStatInit();            /* Compute CPU capacity with no task
running */
      .
      OSTaskCreate(_);         /* Create the other tasks
*/
      OSTaskCreate(_);
      .
      for (;;) {
         .
         .
      }
}
```

OSTaskChangePrio()

```
INT8U OSTaskChangePrio(INT8U oldprio, INT8U newprio);
```

Chapter	*File*	*Called from*	*Code enabled by*
4	OS_TASK.C	Task only	OS_TASK_CHANGE_PRIO_EN

`OSTaskChangePrio()` changes the priority of a task.

Arguments

`oldprio` is the priority number of the task to change.

`newprio` is the new task's priority.

Returned Value

`OSTaskChangePrio()` returns one of the following error codes:

`OS_NO_ERR`	if the task's priority is changed.
`OS_PRIO_INVALID`	if either the old priority or the new priority is equal to or exceeds `OS_LOWEST_PRIO`.
`OS_PRIO_EXIST`	if `newprio` already exists.
`OS_PRIO_ERR`	if no task with the specified old priority exists (i.e., the task specified by `oldprio` does not exist).

Notes/Warnings

1. The desired priority must not already have been assigned; otherwise, an error code is returned. Also, `OSTaskChangePrio()` verifies that the task to change exists.

Example

```
void TaskX (void *data)
{
      INT8U  err;

      for (;;) {
         .
         .
         err = OSTaskChangePrio(10, 15);
         .
         .
      }
}
```

OSTaskCreate()

```
INT8U OSTaskCreate(void  (*task)(void *pd),
                   void   *pdata,
                   OS_STK *ptos,
                   INT8U   prio);
```

Chapter	*File*	*Called from*	*Code enabled by*
4	OS_TASK.C	Task or startup code	OS_TASK_CREATE_EN

`OSTaskCreate()` creates a task so it can be managed by _C/OS-II. Tasks can be created either prior to the start of multitasking or by a running task. A task cannot be created by an ISR. A task must be written as an infinite loop, as shown below, and must not return.

`OSTaskCreate()` is used for backward compatibility with µC/OS and when the added features of `OSTaskCreateExt()` are not needed.

Depending on how the stack frame is built, your task has interrupts either enabled or disabled. You need to check with the processor-specific code for details.

```
void Task (void *pdata)
{
      .                    /* Do something with 'pdata'
*/
      for (;;) {           /* Task body, always an infinite loop.
*/
         .
         .
         /* Must call one of the following services:
*/
         /*    OSMboxPend()
*/
         /*    OSFlagPend()
*/
         /*    OSMutexPend()
*/
         /*    OSQPend()
*/
         /*    OSSemPend()
*/
         /*    OSTimeDly()
*/
         /*    OSTimeDlyHMSM()
*/
         /*    OSTaskSuspend()     (Suspend self)
*/
         /*    OSTaskDel()         (Delete  self)
*/
         .
         .
      }
}
```

Arguments

`task` is a pointer to the task's code.

`pdata` is a pointer to an optional data area used to pass parameters to the task when it is created. Where the task is concerned, it thinks it is invoked and passes the argument `pdata`. `pdata` can be used to pass arguments to the task created. For example, you can create a generic task that handles an asynchronous serial port. `pdata` can be used to pass this task information about the serial port it has to manage: the port address, the baud rate, the number of bits, the parity, and more.

`ptos` is a pointer to the task's top-of-stack. The stack is used to store local variables, function parameters, return addresses, and CPU registers during an interrupt. The size of the stack is determined by the task's requirements and the anticipated interrupt nesting. Determining the size of the stack involves knowing how many bytes are required for storage of local variables for the task itself and all nested functions, as well as requirements for interrupts (accounting for nesting). If the configuration constant `OS_STK_GROWTH` is set to 1, the stack is assumed to grow downward (i.e., from high to low memory). `ptos` thus needs to point to the highest *valid* memory location on the stack. If `OS_STK_GROWTH` is set to 0, the stack is assumed to grow in the opposite direction (i.e., from low to high memory).

`prio` is the task priority. A unique priority number must be assigned to each task, and the lower the number, the higher the priority (i.e., the task importance).

Returned Value

`OSTaskCreate()` returns one of the following error codes:

`OS_NO_ERR`	if the function is successful.
`OS_PRIO_EXIST`	if the requested priority already exists.
`OS_PRIO_INVALID`	if `prio` is higher than `OS_LOWEST_PRIO`.
`OS_NO_MORE_TCB`	if µC/OS-II doesn't have any more `OS_TCB`s to assign.

Notes/Warnings

1. The stack for the task must be declared with the `OS_STK` type.
2. A task must always invoke one of the services provided by µC/OS-II to wait for time to expire, suspend the task, or wait for an event to occur (wait on a mailbox, queue, or semaphore). This allows other tasks to gain control of the CPU.
3. You should not use task priorities `0`, `1`, `2`, `3`, `OS_LOWEST_PRIO-3`, `OS_LOWEST_PRIO-2`, `OS_LOWEST_PRIO-1`, and `OS_LOWEST_PRIO` because they are reserved for use by µC/OS-II. This leaves you with up to 56 application tasks.

Example 1

This example shows that the argument that `Task1()` receives is not used, so the pointer `pdata` is set to `NULL`. Note that I assume the stack grows from high to low memory because I pass the address of the highest valid memory location of the stack `Task1Stk[]`. If the stack grows in the opposite direction for the processor you are using, pass `&Task1Stk[0]` as the task's top-of-stack.

Assigning `pdata` to itself is used to prevent compilers from issuing a warning about the fact that `pdata` is not being used. In other words, if I had not added this line, some compilers would have complained about 'WARNING - variable `pdata` not used.'

```
OS_STK  Task1Stk[1024];

void main (void)
{
      INT8U err;

      .
      OSInit();                /* Initialize µC/OS-II             */
      .
      OSTaskCreate(Task1,
                   (void *)0,
                   &Task1Stk[1023],
                   25);
      .
      OSStart();               /* Start Multitasking              */
}

void Task1 (void *pdata)
{
      pdata = pdata;            /* Prevent compiler warning      */
      for (;;) {
         .                      /* Task code                     */
         .
      }
}
```

Example 2

You can create a generic task that can be instantiated more than once. For example, a task that handles a serial port could be passed the address of a data structure that characterizes the specific port (i.e., port address and baud rate). Note that each task has its own stack space and its own (different) priority. In this example, I arbitrarily decided that COM1 is the most important port of the two.

```
OS_STK    *Comm1Stk[1024];
COMM_DATA  Comm1Data;           /* Data structure containing COMM port
*/
                                /* Specific data for channel 1
*/

OS_STK    *Comm2Stk[1024];
COMM_DATA  Comm2Data;           /* Data structure containing COMM port
*/
                                /* Specific data for channel 2
*/

void main (void)
{
   INT8U err;

   .
   OSInit();                    /* Initialize µC/OS-II
*/
   .
                                /* Create task to manage COM1
*/
   OSTaskCreate(CommTask,
                (void *)&Comm1Data,
                &Comm1Stk[1023],
                25);
                                /* Create task to manage COM2
*/
   OSTaskCreate(CommTask,
                (void *)&Comm2Data,
                &Comm2Stk[1023],
                26);
   .
   OSStart();                   /* Start Multitasking
*/
}

void CommTask (void *pdata)      /* Generic communication task
*/
```

```
{
      for (;;) {
         .                        /* Task code
*/
         .
      }
}
```

OSTaskCreateExt()

```
INT8U OSTaskCreateExt(void   (*task)(void *pd),
                      void    *pdata,
                      OS_STK  *ptos,
                      INT8U    prio,
                      INT16U   id,
                      OS_STK  *pbos,
                      INT32U   stk_size,
                      void    *pext,
                      INT16U   opt);
```

Chapter	*File*	*Called from*	*Code enabled by*
4	OS_TASK.C	Task or startup code	N/A

`OSTaskCreateExt()` creates a task to be managed by µC/OS-II. This function serves the same purpose as `OSTaskCreate()`, except that it allows you to specify additional information about your task to µC/OS-II. Tasks can be created either prior to the start of multitasking or by a running task. A task cannot be created by an ISR. A task must be written as an infinite loop, as shown below, and must not return. Depending on how the stack frame is built, your task has interrupts either enabled or disabled. You need to check with the processor-specific code for details. Note that the first four arguments are exactly the same as the ones for `OSTaskCreate()`. This was done to simplify the migration to this new and more powerful function. It is highly recommended that you use `OSTaskCreateExt()` instead of the older `OSTaskCreate()` function because it's much more flexible.

```
void Task (void *pdata)
{
      .                     /* Do something with 'pdata'
*/
      for (;;) {            /* Task body, always an infinite loop.
*/
         .
         .
         /* Must call one of the following services:
*/
         /*    OSMboxPend()
*/
         /*    OSFlagPend()
*/
         /*    OSMutexPend()
*/
         /*    OSQPend()
*/
         /*    OSSemPend()
*/
```

```
          /*    OSTimeDly()
*/
          /*    OSTimeDlyHMSM()
*/
          /*    OSTaskSuspend()     (Suspend self)
*/
          /*    OSTaskDel()         (Delete  self)
*/
          .
          .
      }
}
```

Arguments

`task` is a pointer to the task's code.

`pdata` is a pointer to an optional data area, which is used to pass parameters to the task when it is created. Where the task is concerned, it thinks it is invoked and passes the argument `pdata`. `pdata` can be used to pass arguments to the task created. For example, you can create a generic task that handles an asynchronous serial port. `pdata` can be used to pass this task information about the serial port it has to manage: the port address, the baud rate, the number of bits, the parity, and more.

`ptos` is a pointer to the task's top-of-stack. The stack is used to store local variables, function parameters, return addresses, and CPU registers during an interrupt.

The size of this stack is determined by the task's requirements and the anticipated interrupt nesting. Determining the size of the stack involves knowing how many bytes are required for storage of local variables for the task itself and all nested functions, as well as requirements for interrupts (accounting for nesting).

If the configuration constant `OS_STK_GROWTH` is set to 1, the stack is assumed to grow downward (i.e., from high to low memory). `ptos` thus needs to point to the highest *valid* memory location on the stack. If `OS_STK_GROWTH` is set to 0, the stack is assumed to grow in the opposite direction (i.e., from low to high memory).

`prio` is the task priority. A unique priority number must be assigned to each task: the lower the number, the higher the priority (i.e., the importance) of the task.

`id` is the task's ID number. At this time, the ID is not currently used in any other function and has simply been added in `OSTaskCreateExt()` for future expansion. You should set `id` to the same value as the task's priority.

`pbos` is a pointer to the task's bottom-of-stack. If the configuration constant `OS_STK_GROWTH` is set to 1, the stack is assumed to grow downward (i.e., from high to low memory); thus, `pbos` must point to the lowest valid stack location. If `OS_STK_GROWTH` is set to 0, the stack is assumed to grow in the opposite direction (i.e., from low to high memory); thus, `pbos` must point to the highest valid stack location. `pbos` is used by the stack-checking function `OSTaskStkChk()`.

`stk_size` specifies the size of the task's stack in number of elements. If `OS_STK` is set to `INT8U`, then `stk_size` corresponds to the number of bytes available on the stack. If `OS_STK` is set to `INT16U`, then `stk_size` contains the number of 16-bit entries available on the stack. Finally, if `OS_STK` is set to `INT32U`, then `stk_size` contains the number of 32-bit entries available on the stack.

`pext` is a pointer to a user-supplied memory location (typically a data structure) used as a TCB extension. For example, this user memory can hold the contents of floating-point registers during a context switch, the time each task takes to execute, the number of times the task is switched in, and so on.

`opt` contains task-specific options. The lower 8 bits are reserved by µC/OS-II, but you can use the upper 8 bits for application-specific options. Each option consists of one or more bits. The option is selected when the bit(s) is set. The current version of µC/OS-II supports the following options:

`OS_TASK_OPT_STK_CHK`	specifies whether stack checking is allowed for the task.
`OS_TASK_OPT_STK_CLR`	specifies whether the stack needs to be cleared.
`OS_TASK_OPT_SAVE_FP`	specifies whether floating-point registers are saved. This option is only valid if your processor has floating-point hardware and the processor-specific code saves the floating-point registers.

Refer to `uCOS_II.H` for other options.

Returned Value

`OSTaskCreateExt()` returns one of the following error codes:

`OS_NO_ERR`	if the function is successful.
`OS_PRIO_EXIST`	if the requested priority already exists.
`OS_PRIO_INVALID`	if `prio` is higher than `OS_LOWEST_PRIO`.
`OS_NO_MORE_TCB`	if _C/OS-II doesn't have any more `OS_TCB`s to assign.

Notes/Warnings

1. The stack must be declared with the `OS_STK` type.
2. A task must always invoke one of the services provided by µC/OS-II to wait for time to expire, suspend the task, or wait an event to occur (wait on a mailbox, queue, or semaphore). This allows other tasks to gain control of the CPU.
3. You should not use task priorities `0`, `1`, `2`, `3`, `OS_LOWEST_PRIO-3`, `OS_LOWEST_PRIO-2`, `OS_LOWEST_PRIO-1`, and `OS_LOWEST_PRIO` because they are reserved for use by µC/OS-II. This leaves you with up to 56 application tasks.

Example 1

E1(1) The task control block is extended using a user-defined data structure called `OS_TASK_USER_DATA`, which in this case contains the name of the task as well as other fields.

E1(2) The task name is initialized with the standard library function `strcpy()`.

E1(4) Note that stack checking has been enabled for this task, so you are allowed to call `OSTaskStkChk()`.

E1(3) Also, assume here that the stack grows downward on the processor used (i.e., `OS_STK_GROWTH` is set to 1; `TOS` stands for top-of-stack and `BOS` stands for bottom-of-stack).

```
typedef struct {                    /*  User defined data structure */
(1)
    char    OSTaskName[20];
    INT16U  OSTaskCtr;
    INT16U  OSTaskExecTime;
    INT32U  OSTaskTotExecTime;
} OS_TASK_USER_DATA;

OS_STK           TaskStk[1024];
TASK_USER_DATA   TaskUserData;

void main (void)
{
      INT8U err;

      .
      OSInit();                             /* Initialize µC/OS-II     */
      .
      strcpy(TaskUserData.TaskName, "MyTaskName");  /* Name of task     */
(2)
      err = OSTaskCreateExt(Task,
               (void *)0,
               &TaskStk[1023],              /*  Stack grows down (TOS) */
(3)

               10,
               &TaskStk[0],                 /*  Stack grows down (BOS) */
(3)
               1024,
               (void *)&TaskUserData,       /* TCB Extension           */
               OS_TASK_OPT_STK_CHK);        /*  Stack checking enabled */
(4)
      .
      OSStart();                            /* Start Multitasking      */
}

void Task(void *pdata)
{
      pdata = pdata;                        /* Avoid compiler warning  */
      for (;;) {
         .                                  /* Task code               */
```

```
          .
      }
}
```

Example 2

E2(1) Now create a task, but this time on a processor for which the stack grows upward. The Intel MCS-51 is an example of such a processor. In this case, `OS_STK_GROWTH` is set to 0.

E2(2) Note that stack checking has been enabled for this task so you are allowed to call `OSTaskStkChk()` (`TOS` stands for top-of-stack and `BOS` stands for bottom-of-stack).

```
OS_STK *TaskStk[1024];

void main (void)
{
      INT8U err;

      .
      OSInit();                                /* Initialize µC/OS-II     */
      .
      err = OSTaskCreateExt(Task,
                (void *)0,
                &TaskStk[0],                   /*  Stack grows up (TOS)   */
(1)
                10,
                10,
                &TaskStk[1023],                /*  Stack grows up (BOS)   */
(1)
                1024,
                (void *)0,
                OS_TASK_OPT_STK_CHK);          /*  Stack checking enabled */
(2)
      .
      OSStart();                               /* Start Multitasking      */
}

void Task (void *pdata)
{
      pdata = pdata;                           /* Avoid compiler warning  */
      for (;;) {
         .                                     /* Task code               */
         .
      }
}
```

OSTaskDel()

```
INT8U OSTaskDel(INT8U prio);
```

Chapter	*File*	*Called from*	*Code enabled by*
4	OS_TASK.C	Task only	OS_TASK_DEL_EN

`OSTaskDel()` deletes a task by specifying the priority number of the task to delete. The calling task can be deleted by specifying its own priority number or `OS_PRIO_SELF` (if the task doesn't know its own priority number). The deleted task is returned to the dormant state. The deleted task can be re-created by calling either `OSTaskCreate()` or `OSTaskCreateExt()` to make the task active again.

Arguments

`prio` is the priority number of the task to delete. You can delete the calling task by passing `OS_PRIO_SELF`, in which case the next highest priority task is executed.

Returned Value

`OSTaskDel()` returns one of the following error codes:

`OS_NO_ERR`	if the task doesn't delete itself.
`OS_TASK_DEL_IDLE`	if you try to delete the idle task, which is of course is not allowed.
`OS_TASK_DEL_ERR`	if the task to delete does not exist.
`OS_PRIO_INVALID`	if you specify a task priority higher than `OS_LOWEST_PRIO`.
`OS_TASK_DEL_ISR`	if you try to delete a task from an ISR.

Notes/Warnings

1. `OSTaskDel()` verifies that you are not attempting to delete the µC/OS-II idle task.
2. You must be careful when you delete a task that owns resources. Instead, consider using `OSTaskDelReq()` as a safer approach.

Example

```
void TaskX (void *pdata)
{
      INT8U err;

      for (;;) {
         .
         .
         err = OSTaskDel(10);      /* Delete task with priority 10  */
         if (err == OS_NO_ERR) {
            .                      /* Task was deleted              */
            .
         }
         .
         .
      }
}
```

OSTaskDelReq()

```
INT8U OSTaskDelReq(INT8U prio);
```

Chapter	*File*	*Called from*	*Code enabled by*
4	OS_TASK.C	Task only	OS_TASK_DEL_EN

`OSTaskDelReq()` requests that a task delete itself. Basically, use `OSTaskDelReq()` when you need to delete a task that can potentially own resources (e.g., the task might own a semaphore). In this case, you don't want to delete the task until the resource is released. The requesting task calls `OSTaskDelReq()` to indicate that the task needs to be deleted. Deletion of the task is, however, deferred to the task being deleted. In other words, the task is actually deleted when it regains control of the CPU. For example, suppose Task 10 needs to be deleted. The task wanting to delete this task (example Task 5) calls `OSTaskDelReq(10)`. When Task 10 executes, it calls `OSTaskDelReq(OS_PRIO_SELF)` and monitors the return value. If the return value is `OS_TASK_DEL_REQ`, then Task 10 is asked to delete itself. At this point, Task 10 calls `OSTaskDel(OS_PRIO_SELF)`. Task 5 knows whether Task 10 has been deleted by calling `OSTaskDelReq(10)` and checking the return code. If the return code is `OS_TASK_NOT_EXIST`, then Task 5 knows that Task 10 has been deleted. Task 5 might have to check periodically until `OS_TASK_NOT_EXIST` is returned.

Arguments

`prio` is the task's priority number of the task to delete. If you specify `OS_PRIO_SELF`, you are asking whether another task wants the current task to be deleted.

Returned Value

`OSTaskDelReq()` returns one of the following error codes:

`OS_NO_ERR`	if the task deletion has been registered.
`OS_TASK_NOT_EXIST`	if the task does not exist. The requesting task can monitor this return code to see if the task is actually deleted.
`OS_TASK_DEL_IDLE`	if you ask to delete the idle task (which is obviously not allowed).
`OS_PRIO_INVALID`	if you specify a task priority higher than `OS_LOWEST_PRIO` or do not specify `OS_PRIO_SELF`.
`OS_TASK_DEL_REQ`	if a task (possibly another task) requests that the running task be deleted.

Notes/Warnings

1. `OSTaskDelReq()` verifies that you are not attempting to delete the µC/OS-II idle task.

Example

```
void TaskThatDeletes (void *pdata)   /* My priority is 5
*/
{
      INT8U err;

      for (;;) {
         .
         .
         err = OSTaskDelReq(10);     /* Request task #10 to delete itself
*/
         if (err == OS_NO_ERR) {
            while (err != OS_TASK_NOT_EXIST) {
               err = OSTaskDelReq(10);
               OSTimeDly(1);         /* Wait for task to be deleted
*/
            }
            .                        /* Task #10 has been deleted
*/
         }
         .
         .
      }
}

void TaskToBeDeleted (void *pdata)   /* My priority is 10
*/
{
   .
   .
   pdata = pdata;
   for (;;) {
      OSTimeDly(1);
      if (OSTaskDelReq(OS_PRIO_SELF) == OS_TASK_DEL_REQ) {
         /* Release any owned resources;
*/
         /* De-allocate any dynamic memory;
*/
         OSTaskDel(OS_PRIO_SELF);
      }
   }
}
```

OSTaskNameGet()

```
INT8U OSTaskNameGet(INT8U prio, char *pname, INT8U *err);
```

Chapter	File	Called from	Code enabled by
New in V2.60	OS_TASK.C	Task or ISR	OS_TASK_NAME_SIZE

`OSTaskNameGet()` allows you to obtain the name that you assigned to a task. The name is an ASCII string and the size of the name can contain up to `OS_TASK_NAME_SIZE` characters (including the `NUL` termination). This function is typically used by a debugger to allow associating a name to a task.

Arguments

`prio` is the priority of the task from which you would like to obtain the name from. If you specify `OS_PRIO_SELF`, you would obtain the name of the current task.

`pname` is a pointer to an ASCII string that will receive the name of the task. The string must be able to hold at least `OS_TASK_NAME_SIZE` characters (including the `NUL` character).

`err` a pointer to an error code and can be any of the following:

`OS_NO_ERR`	If the name of the task was copied to the array pointed to by `pname`.
`OS_TASK_NOT_EXIST`	The task you specified was not created or has been deleted.
`OS_PRIO_INVALID`	If you specified an invalid priority - a priority higher than the idle task (`OS_LOWEST_PRIO`) or you didn't specify `OS_PRIO_SELF`.

Returned Values

The size of the ASCII string placed in the array pointed to by `pname` or `0` if an error is encountered.

Notes/Warnings

1. The task must be created before you can use this function and obtain the name of the task.
2. You must ensure that you have sufficient storage in the destination string to hold the name of the task.

Example

```
char   EngineTaskName[30];

void Task (void *pdata)
{
    INT8U     err;
    INT8U     size;

    pdata = pdata;
    for (;;) {
        size = OSTaskNameGet(OS_PRIO_SELF, &EngineTaskName[0], &err);
        .
        .
    }
```

```
}
```

OSTaskNameSet()

```
void OSTaskNameSet(INT8U prio, char *pname, INT8U *err);
```

Chapter	File	Called from	Code enabled by
New in V2.60	OS_TASK.C	Task or ISR	OS_TASK_NAME_SIZE

OSTaskNameSet() allows you to assign a name to a task. The name is an ASCII string and the size of the name can contain up to OS_TASK_NAME_SIZE characters (including the NUL termination). This function is typically used by a debugger to allow associating a name to a task.

Arguments

prio is the priority of the task that you want to name. If you specify OS_PRIO_SELF, you would set the name of the current task.

pname is a pointer to an ASCII string that hold the name of the task. The string must be smaller than or equal to OS_TASK_NAME_SIZE characters (including the NUL character).

err a pointer to an error code and can be any of the following:

OS_NO_ERR	If the name of the task was set.
OS_TASK_NOT_EXIST	The task you specified was not created or has been deleted.
OS_PRIO_INVALID	If you specified an invalid priority - a priority higher than the idle task (OS_LOWEST_PRIO) or you didn't specify OS_PRIO_SELF.

Returned Values

None.

Notes/Warnings

1. The task must be created before you can use this function to set the name of the task.

Example

```
void Task (void *pdata)
{
    INT8U     err;

    pdata = pdata;
    for (;;) {
        OSTaskNameSet(OS_PRIO_SELF, "Engine Task", &err);
        .
        .
    }
}
```

OSTaskQuery()

```
INT8U OSTaskQuery(INT8U prio, OS_TCB *pdata);
```

Chapter	*File*	*Called from*	*Code enabled by*
4	OS_TASK.C	Task or ISR	N/A

OSTaskQuery() obtains information about a task. Your application must allocate an OS_TCB data structure to receive a snapshot of the desired task's control block. Your copy contains *every* field in the OS_TCB structure. You should be careful when accessing the contents of the OS_TCB structure, especially OSTCBNext and OSTCBPrev, because they point to the next and previous OS_TCBs in the chain of created tasks, respectively. You could use this function to provide a debugger kernel awareness.

Arguments

prio is the priority of the task from which you wish to obtain data. You can obtain information about the calling task by specifying OS_PRIO_SELF.

pdata is a pointer to a structure of type OS_TCB, which contains a copy of the task's control block.

Returned Value

OSTaskQuery() returns one of these error codes:

OS_NO_ERR	if the call is successful.
OS_PRIO_ERR	if you try to obtain information from an invalid task.
OS_PRIO_INVALID	if you specify a priority higher than OS_LOWEST_PRIO.

Notes/Warnings

1. The fields in the task control block depend on the following configuration options (see OS_CFG.H):
   - OS_TASK_CREATE_EN
   - OS_Q_EN
   - OS_FLAG_EN
   - OS_MBOX_EN
   - OS_SEM_EN
   - OS_TASK_DEL_EN

Example

```
void Task (void *pdata)
{
      OS_TCB  task_data;
      INT8U   err;
      void   *pext;
      INT8U   status;

      pdata = pdata;
      for (;;) {
         .
         .
         err = OSTaskQuery(OS_PRIO_SELF, &task_data);
         if (err == OS_NO_ERR) {
            pext   = task_data.OSTCBExtPtr; /* Get TCB extension pointer
*/
            status = task_data.OSTCBStat;   /* Get task status
*/
            .
            .
         }
         .
         .
      }
   }
```

OSTaskResume()

```
INT8U OSTaskResume(INT8U prio);
```

Chapter	*File*	*Called from*	*Code enabled by*
4	OS_TASK.C	Task only	OS_TASK_SUSPEND_EN

`OSTaskResume()` resumes a task suspended through the `OSTaskSuspend()` function. In fact, `OSTaskResume()` is the only function that can unsuspend a suspended task.

Arguments

`prio` specifies the priority of the task to resume.

Returned Value

`OSTaskResume()` returns one of the these error codes:

`OS_NO_ERR`	if the call is successful.
`OS_TASK_RESUME_PRIO`	if the task you are attempting to resume does not exist.
`OS_TASK_NOT_SUSPENDED`	if the task to resume has not been suspended.
`OS_PRIO_INVALID`	if `prio` is higher or equal to `OS_LOWEST_PRIO`.

Notes/Warnings

none

Example

```
void TaskX (void *pdata)
{
      INT8U err;

      for (;;) {
         .
         .
         err = OSTaskResume(10);        /* Resume task with priority 10
*/
         if (err == OS_NO_ERR) {
            .                           /* Task was resumed
*/
            .
         }
         .
         .
      }
}
```

OSTaskStkChk()

```
INT8U OSTaskStkChk(INT8U prio, OS_STK_DATA *pdata);
```

Chapter	*File*	*Called from*	*Code enabled by*
4	OS_TASK.C	Task code	OS_TASK_CREATE_EXT

`OSTaskStkChk()` determines a task's stack statistics. Specifically, it computes the amount of free stack space, as well as the amount of stack space used by the specified task. This function requires that the task be created with `OSTaskCreateExt()` and that you specify `OS_TASK_OPT_STK_CHK` in the `opt` argument.

Stack sizing is done by walking from the bottom of the stack and counting the number of 0 entries on the stack until a nonzero value is found. Of course, this assumes that the stack is cleared when the task is created. For that purpose, you need to set `OS_TASK_OPT_STK_CLR` to 1 as an option when you create the task. You could set `OS_TASK_OPT_STK_CLR` to 0 if your startup code clears all RAM and you never delete your tasks. This reduces the execution time of `OSTaskCreateExt()`.

Arguments

`prio` is the priority of the task about which you want to obtain stack information. You can check the stack of the calling task by passing `OS_PRIO_SELF`.

`pdata` is a pointer to a variable of type `OS_STK_DATA`, which contains the following fields:

```
    INT32U OSFree;        /* Number of bytes free on the stack
*/
    INT32U OSUsed;        /* Number of bytes used on the stack
*/
```

Returned Value

`OSTaskStkChk()` returns one of the these error codes:

`OS_NO_ERR`	if you specify valid arguments and the call is successful.
`OS_PRIO_INVALID`	if you specify a task priority higher than `OS_LOWEST_PRIO` or you don't specify `OS_PRIO_SELF`.
`OS_TASK_NOT_EXIST`	if the specified task does not exist.
`OS_TASK_OPT_ERR`	if you do not specify `OS_TASK_OPT_STK_CHK` when the task was created by `OSTaskCreateExt()` or if you create the task by using `OSTaskCreate()`.

Notes/Warnings

1. Execution time of this task depends on the size of the task's stack and is thus nondeterministic.
2. Your application can determine the total task stack space (in number of bytes) by adding the two fields `.OSFree` and `.OSUsed` of the `OS_STK_DATA` data structure.
3. Technically, this function can be called by an ISR, but because of the possibly long execution time, it is not advisable.

Example

```
void Task (void *pdata)
{
      OS_STK_DATA stk_data;
      INT32U      stk_size;

      for (;;) {
         .
         .
         err = OSTaskStkChk(10, &stk_data);
         if (err == OS_NO_ERR) {
            stk_size = stk_data.OSFree + stk_data.OSUsed;
         }
         .
         .
      }
}
```

OSTaskSuspend()

```
INT8U OSTaskSuspend(INT8U prio);
```

Chapter	*File*	*Called from*	*Code enabled by*
4	OS_TASK.C	Task only	OS_TASK_SUSPEND_EN

OSTaskSuspend() suspends (or blocks) execution of a task unconditionally. The calling task can be suspended by specifying its own priority number or OS_PRIO_SELF if the task doesn't know its own priority number. In this case, another task needs to resume the suspended task. If the current task is suspended, rescheduling occurs, and µC/OS-II runs the next highest priority task ready to run. The only way to resume a suspended task is to call OSTaskResume().

Task suspension is additive, which means that if the task being suspended is delayed until *n* ticks expire, the task is resumed only when both the time expires and the suspension is removed. Also, if the suspended task is waiting for a semaphore and the semaphore is signaled, the task is removed from the semaphore-wait list (if it is the highest priority task waiting for the semaphore), but execution is not resumed until the suspension is removed.

Arguments

prio specifies the priority of the task to suspend. You can suspend the calling task by passing OS_PRIO_SELF, in which case, the next highest priority task is executed.

Returned Value

OSTaskSuspend() returns one of the these error codes:

OS_NO_ERR	if the call is successful.
OS_TASK_SUSPEND_IDLE	if you attempt to suspend the _C/OS-II idle task, which is not allowed.
OS_PRIO_INVALID	if you specify a priority higher than the maximum allowed (i.e., you specify a priority of OS_LOWEST_PRIO or more) or you don't specify OS_PRIO_SELF.
OS_TASK_SUSPEND_PRIO	if the task you are attempting to suspend does not exist.

Notes/Warnings

1. OSTaskSuspend() and OSTaskResume() must be used in pairs.
2. A suspended task can only be resumed by OSTaskResume().

Example

```
void TaskX (void *pdata)
{
      INT8U err;

      for (;;) {
         .
         .
         err = OSTaskSuspend(OS_PRIO_SELF);      /* Suspend current task
*/
         .                    /* Execution continues when ANOTHER task ..
*/
         .                    /* .. explicitly resumes this task.
*/
         .
      }
}
```

OSTimeDly()

```
void OSTimeDly(INT16U ticks);
```

Chapter	*File*	*Called from*	*Code enabled by*
5	OS_TIME.C	Task only	N/A

`OSTimeDly()` allows a task to delay itself for an integral number of clock ticks. Rescheduling always occurs when the number of clock ticks is greater than zero. Valid delays range from one to 65,535 ticks. A delay of 0 means that the task is not delayed, and `OSTimeDly()` returns immediately to the caller. The actual delay time depends on the tick rate (see `OS_TICKS_PER_SEC` in the configuration file `OS_CFG.H`).

Arguments

`ticks` is the number of clock ticks to delay the current task.

Returned Value

none

Notes/Warnings

1. Note that calling this function with a value of 0 results in no delay, and the function returns immediately to the caller.
2. To ensure that a task delays for the specified number of ticks, you should consider using a delay value that is one tick higher. For example, to delay a task for at least 10 ticks, you should specify a value of 11.

Example

```
void TaskX (void *pdata)
{
      for (;;) {
         .
         .
         OSTimeDly(10);                /* Delay task for 10 clock ticks */
         .
         .
      }
}
```

OSTimeDlyHMSM()

```
void OSTimeDlyHMSM (INT8U hours, INT8U minutes, INT8U seconds, INT8U
milli);
```

Chapter	*File*	*Called from*	*Code enabled by*
5	OS_TIME.C	Task only	N/A

`OSTimeDlyHMSM()` allows a task to delay itself for a user-specified amount of time specified in hours, minutes, seconds, and milliseconds. This format is more convenient and natural than ticks. Rescheduling always occurs when at least one of the parameters is nonzero.

Arguments

`hours` is the number of hours the task is delayed. The valid range of values is 0 to 255.

`minutes` is the number of minutes the task is delayed. The valid range of values is 0 to 59.

`seconds` is the number of seconds the task is delayed. The valid range of values is 0 to 59.

`milli` is the number of milliseconds the task is delayed. The valid range of values is 0 to 999. Note that the resolution of this argument is in multiples of the tick rate. For instance, if the tick rate is set to 100Hz, a delay of 4ms results in no delay. The delay is rounded to the nearest tick. Thus, a delay of 15ms actually results in a delay of 20ms.

Returned Value

`OSTimeDlyHMSM()` returns one of the these error codes:

`OS_NO_ERR`	if you specify valid arguments and the call is successful.
`OS_TIME_INVALID_MINUTES`	if the minutes argument is greater than 59.
`OS_TIME_INVALID_SECONDS`	if the seconds argument is greater than 59.
`OS_TIME_INVALID_MILLI`	if the milliseconds argument is greater than 999.
`OS_TIME_ZERO_DLY`	if all four arguments are 0.

Notes/Warnings

1. Note that `OSTimeDlyHMSM(0,0,0,0)` (i.e., hours, minutes, seconds, milliseconds) results in no delay, and the function returns to the caller. Also, if the total delay time is longer than 65,535 clock ticks, you cannot abort the delay and resume the task by calling `OSTimeDlyResume()`.

Example

```
void TaskX (void *pdata)
{
      for (;;) {
         .
         .
         OSTimeDlyHMSM(0, 0, 1, 0);  /* Delay task for 1 second */
         .
         .
      }
}
```

OSTimeDlyResume()

```
INT8U OSTimeDlyResume(INT8U prio);
```

Chapter	*File*	*Called from*	*Code enabled by*
5	OS_TIME.C	Task only	N/A

`OSTimeDlyResume()` resumes a task that has been delayed through a call to either `OSTimeDly()` or `OSTimeDlyHMSM()`.

Arguments

`prio` specifies the priority of the task to resume.

Returned Value

`OSTimeDlyResume()` returns one of the these error codes:

`OS_NO_ERR`	if the call is successful.
`OS_PRIO_INVALID`	if you specify a task priority greater than `OS_LOWEST_PRIO`.
`OS_TIME_NOT_DLY`	if the task is not waiting for time to expire.
`OS_TASK_NOT_EXIST`	if the task has not been created.

Notes/Warnings

1. Note that you must not call this function to resume a task that is waiting for an event with timeout. This situation makes the task look like a timeout occurred (unless you desire this effect).
2. You cannot resume a task that has called `OSTimeDlyHMSM()` with a combined time that exceeds 65,535 clock ticks. In other words, if the clock tick runs at 100Hz, you cannot resume a delayed task that called `OSTimeDlyHMSM(0, 10, 55, 350)` or higher.

   ```
   (10 minutes * 60 + (55 + 0.35) seconds) * 100 ticks/second
   ```

Example

```
void TaskX (void *pdata)
{
   INT8U err;

   pdata = pdata;
   for (;;) {
      .
      err = OSTimeDlyResume(10);          /* Resume task with
priority 10     */
      if (err == OS_NO_ERR) {
         .                                /* Task was resumed
*/
         .
      }
      .
   }
}
```

OSTimeGet()

```
INT32U OSTimeGet(void);
```

Chapter	*File*	*Called from*	*Code enabled by*
5	OS_TIME.C	Task or ISR	N/A

`OSTimeGet()` obtains the current value of the system clock. The system clock is a 32-bit counter that counts the number of clock ticks since power was applied or since the system clock was last set.

Arguments

none

Returned Value

The current system clock value (in number of ticks).

Notes/Warnings

none

Example

```
void TaskX (void *pdata)
{
       INT32U clk;

       for (;;) {
          .
          .
          clk = OSTimeGet();  /* Get current value of system clock */
          .
          .
       }
}
```

OSTimeSet()

```
void OSTimeSet(INT32U ticks);
```

Chapter	*File*	*Called from*	*Code enabled by*
5	OS_TIME.C	Task or ISR	N/A

`OSTimeSet()` sets the system clock. The system clock is a 32-bit counter that counts the number of clock ticks since power was applied or since the system clock was last set.

Arguments

`ticks` is the desired value for the system clock, in ticks.

Returned Value

none

Notes/Warnings

none

Example

```
void TaskX (void *pdata)
{
      for (;;) {
          .
          .
          OSTimeSet(0L);    /* Reset the system clock  */
          .
          .
      }
}
```

OSTimeTick()

```
void OSTimeTick(void);
```

Chapter	*File*	*Called from*	*Code enabled by*
5	OS_TIME.C	Task or ISR	N/A

`OSTimeTick()` processes a clock tick. µC/OS-II checks all tasks to see if they are either waiting for time to expire [because they called `OSTimeDly()` or `OSTimeDlyHMSM()`] or waiting for events to occur until they timeout.

Arguments

none

Returned Value

none

Notes/Warnings

1. The execution time of `OSTimeTick()` is directly proportional to the number of tasks created in an application. `OSTimeTick()` can be called by either an ISR or a task. If called by a task, the task priority should be very high (i.e., have a low priority number) because this function is responsible for updating delays and timeouts.

Example

(Intel 80x86, real mode, large model)

```
_OSTickISR PROC FAR
                PUSHA                                ; Save processor context
                PUSH ES
                PUSH DS
;
                MOV    AX, SEG(_OSIntNesting)        ; Reload DS
                MOV    DS, AX
                INC    BYTE PTR DS:_OSIntNesting     ; Notify µC/OS-II of ISR
;
                CMP    BYTE PTR DS:_OSIntNesting, 1  ; if (OSIntNesting == 1)
                JNE    SHORT _OSTickISR1
                MOV    AX, SEG(_OSTCBCur)            ;     Reload DS
                MOV    DS, AX
                LES    BX, DWORD PTR DS:_OSTCBCur    ;     OSTCBCur->OSTCBStkPtr = SS:SP
                MOV    ES:[BX+2], SS                 ;
                MOV    ES:[BX+0], SP                 ;
                CALL  FAR  PTR  _OSTimeTick          ; Process clock tick
                .                                    ; User Code to clear interrupt
                .
                CALL FAR PTR _OSIntExit              ; Notify µC/OS-II of end of ISR
                POP  DS                              ; Restore processor registers
                POP  ES
                POPA
;
                IRET                                ; Return to interrupted task
```

```
_OSTickISR     ENDP
```

OSVersion()

```
INT16U OSVersion(void);
```

Chapter	*File*	*Called from*	*Code enabled by*
3	OS_CORE.C	Task or ISR	N/A

`OSVersion()` obtains the current version of µC/OS-II.

Arguments

none

Returned Value

The version is returned as *x.yy* multiplied by 100. For example, v2.60 is returned as 260.

Notes/Warnings

none

Example

```
void TaskX (void *pdata)
{
       INT16U os_version;

       for (;;) {
          .
          .
          os_version = OSVersion();  /* Obtain µC/OS-II's version   */
          .
          .
       }
}
```
